November 7 and 8.—The first show of Chrysanthemums which has been held in the new Horticultural Hall, Westminster, was a decided success. The large hall was filled with blooms of all the various types, and the general effect from the dais was very bright and pleasing. Although following such an exceptionally hot and dry summer it is not entirely a Chrysanthemum year, the best of the many large exhibition blooms were of very high quality, and in most instances the competition was, as usual, very keen. To the older school, at any rate, there was a welcome improvement in the quality of the Incurved blooms which were thought to be equal to those of the days when the type was dominant at the shows. The groups of Chrysanthemums, arranged on the floor, were very attractive, but the competition with specimen plants was very disappointing. The many fine trade displays were a most valuable feature of the show and they attracted a deal of well-deserved admiration. As is usual at the Annual Show, a large number of novelties were submitted to the Floral Committee, which awarded nine First Class Certificates. All the arrangements worked smoothly, and although there was a large attendance, there was a welcome absence of the congestion of the first day of former years.

First Class Certificates.

Crimson Model.—A large, well-formed Single. The substantial florets of medium width recurve gracefully at the tips. The colour of this splendid variety is a rich crimson, lightly flushed with maroon at the tips of the florets. Shown by Mr. G. Carpenter, West Hall Gardens, Byfleet.

Hebe.—A large, pinkish-mauve Single which has a narrow, white zone. Shown by Mr. H. Shoesmith, junr.

Florence Bigland.—A market-sized, yellow Japanese variety with florets of medium width. Shown by Mr. H. Shoesmith, junr.

J. Moffatt.—A splendid, large, Single Chrysanthemum with broad, substantial florets heavily stippled with rose-crimson on yellow ground. There is a narrow, yellow zone. Shown by Mr. W. Turnham.

Rise of Day.—A magnificent Incurved Japanese variety of the best exhibition type. The broad, substantial florets curl very attractively, and mostly show the uncommon buff colouring which is lightly tinted with rose-pink. Shown by Messrs. Keith Luxford and Co.

Severn.—A fine, large, Japanese variety. The broad florets are of rich chestnut colour and the dull yellow reverse shows in the centre of the flower and on the more mature outer florets. Shown by Mr. H. Woolman.

Thames.—A large, Japanese variety of exhibition size, and blush-mauve colouring, with a silvery reverse. Shown by Mr. H. Woolman.

Yellow Monument.—A good, medium, yellow sport from the well-known white, Incurved variety. Shown by Mr. T. Stevenson.

Lucifer.—A market Japanese variety of glowing, rich crimson colour. Shown by Mr. H. Shoesmith, junr.

Open Classes: Trade excluded.

There were four entries in the class for thirty-six Japanese blooms, in twelve varieties, staged in vases. The quality was exceedingly good, and the first prize exhibit of the Dowager Lady Annaly (gr. Mr. D. Cameron), Holdenby House, Northampton, was a triumph of cultural skill. The varieties were Miss Ada Ellis, Red Majestic, Queen Mary, Birmingham, Victory, W. Rigby, Duchess of Westminster, Majestic, Yellow Majestic and Aquitania. The second prize was awarded to The Hon. Sir John Ward, K.C.V.O. (gr. Mr. C. Beckett), Chilton, Hungerford, whose very best blooms were W. Rigby, Red Majestic, Charles Davis, Mrs. Algernon Davis, Julia and Mrs. A. Holden. Viscount Hambleden (gr. Mr. W. Turnham), Greenlands, Henley-on-Thames, was third, and he showed excellent vases of Princess Mary, Majestic, Queen Mary, Charles Davis, Red Majestic, Marjorie Woolman, Mrs. Gibson and R. C. Pulling.

Only three exhibitors staged eighteen Japanese blooms in six varieties of stipulated colours, and here the Dowager Lady Annaly was again first, with another splendid exhibit. The varieties were Mrs. P. Murray, Majestic, Yellow Majestic, Miss Ada Ellis, Birmingham and Queen Mary. The Hon. Sir John Ward was a good second, and his collection was composed of Queen Mary, Red Majestic, Julia, Yellow Majestic, Birmingham and Mrs. Algernon Davis. Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, who was third, had fine blooms of Red Majestic, Charles Davis and Thalia.

Only the Hon. Sir John Ward staged an exhibit in the class for twelve varieties which had received the Society's First Class Certificate during 1927 and 1928. This was a very disappointing class, and it would seem that the only large Japanese varieties of the two years worth growing are Mrs. F. C. Maples, broad petalled, incurving Japanese; Blackpool, crimson-maroon; Mrs. K. Luxford, a compact, narrow-petalled, rich chestnut, and Charles Davis, long, drooping, rich yellow; for the others were poor.

The Holmes Memorial Challenge Cup class was not so strong as usual, for there were only two exhibitors, who staged exceedingly good blooms, although both were a little weak in the crimson varieties. The Hon. Sir John Ward was first, and his exhibit included Victory, Mrs. G. Drabble, Mrs. Harold Wells, Queen Mary and Mrs. A. Brown, whites; W. Rigby, Lady E. Miller, Charles Davis and Yellow Majestic, yellows; Miss D. C. Athron, Majestic, Marjorie Woolman, Red Majestic and Worcestershire, shades of chestnut. In his second prize exhibit, Viscount Hambleden staged particularly good blooms of R. C. Pulling, Tom Abbott, W. Rigby and Golden Majestic, yellow; Red Majestic, Edith Cavell, Majestic, chestnut shades, and Mrs. G. Drabble, Queen Mary and Louisa Pockett.

There were seven exhibits of twenty-four Japanese varieties, and in this class the colours were better balanced, and those of bright colours were very prominent. Lady Melchett, D.B.E. (gr. Mr. W. Petty), Melchet Court, Romsey, was first, showing especially good blooms of Southampton, Birmingham, W. Rigby, Miss Ada Ellis, Victory, Mrs. R. C. Pulling, Julia, Princess Mary, Charles Davis, and a good crimson seedling of Mrs. George Monro type. In a good second prize exhibit the Dowager Lady Annaly staged Mrs. G. Monro, Birmingham and Thalia, rich crimsons; W. Rigby, Mrs. R. C. Pulling, Yellow Majestic and Princess Mary, good yellows; Victory and Queen Mary, whites; Majestic, Aquitania, Julia and Marjorie Woolman, shades of chestnut. Mrs. Thomson (gr. Mr. L. Barnard), Long Walk House, Windsor, was a good third, and her very best blooms were of Aquitania, Mr. T. Slack, Red Majestic, bright chestnut shades; Princess Mary, Boule d'Or and Yellow Majestic, rich yellows.

The experimental class was again very successful, and the larger boards which allowed ten inches for each bloom displayed the beauty of the excellent specimens to the fullest advantage. The first prize was won by the Dowager Lady Annaly with a superb exhibit which included Majestic, Mrs. B. Carpenter, Southampton, Miss Ada Ellis, Red Majestic and Thalia, of great merit. Mrs. C. Pearson (gr. Mr. C. Hodgson), Acton Place, Sudbury, Suffolk, was a good second in this important class. The very best specimens were of Marjorie Woolman, Mrs. C. Davis, W. Rigby, Red Majestic and Thomas W. Pockett. Mrs. Thomson, who was third, won the first prize in the class for six Japanese blooms with magnificent specimens of Majestic, Red Majestic, Yellow Majestic, Birmingham, Queen Mary and Mrs. B. Carpenter. The second prize exhibit of Mr. George Curran, Nottingham, was of uneven quality, but he had really superb blooms of Lady Talbot, Hugh Mitchell, Tom Abbott and William Turner. The third prize was awarded to James Armitage, Esq. (gr. Mr. R. Jones), Blora, Harrogate, for six very large blooms which, however, lacked the high quality of the first and second prize winners.

The colour classes, which each require three blooms of one variety staged in vases, were especially successful, as well as instructive, and many magnificent blooms were shown. The best white variety was Mrs. Gilbert Drabble, shown by the Dowager Lady Annaly; Louisa Pockett, by Lady Juliet Duff (gr. Mr. H. Weaver), Coombe Court, Kingston, Surrey, was the second best; and Mrs. Harold Wells, shown by the Hon. Sir John Ward, was third. Superb blooms of Birmingham, shown by J. H. Plaxford, Esq. (gr. Mr. A. Johnson), Manor House, Great Nelmes, Hornchurch, was the best crimson variety, while Mrs. George Monro, shown by the Dowager Lady Annaly, was second in this excellent class, and Mr. A. Holden, shown by the Hon. Sir John Ward, was third.

The Dowager Lady Annaly showed, in Princess Mary, the best three yellows. Viscount Hambleden was second with Yellow Majestic, and Mr. George Curran was third, with Shirley Golden. The class for any colour other than crimson, yellow or white, was also well contested, and here J. H. Plaxford, Esq., was first with Thomas W. Pockett; Mrs. C. Pearson was second with Majestic, and the Dowager Lady Annaly was third with Red Majestic.

The Incurved varieties were of decidedly higher quality than of recent years. The best vase of six blooms in not fewer than three varieties, was shown by James Armitage, Esq., who included beautiful specimens of Mrs. P. Wiseman, Romance, Progress and Calypso. Mr. George Curran, was a good second, and he had fine blooms of Romance, Percy Wiseman and Progress.

The Holmes Memorial Cup was won by Mr. George Curran, whose eighteen splendid blooms in vases included Progress, Percy Dove, Mrs. Brice, Ondine, Romance and Percy Wiseman. Gus Mayer, Esq., (gr. Mr. Cottam), Woldingham, was second, with Monument, Ondine and Romance. The same high quality was continued in the Incurved varieties shown on boards, where the best twelve were shown by Mr. George Curran, who included Mrs. Percy Wiseman, Romance, Ondine and Mrs. Brice. Gus Mayer, Esq., was second. Of the four exhibits of six Incurved varieties, the best was shown by James Armitage, Esq., who had excellent blooms of Mrs. Percy Wiseman, Advance, Calypso, Ondine, Mrs. F. Ashworth and Progress. Mr. George Curran, was second with Mrs. G. Danger and Ondine of splendid shape; and Gus Mayer, Esq., Whistler's Wood, Woldingham, was third.

The best six vases of Decorative Chrysanthemums were shown by Mrs. Winterbottom (gr. Mr. G. Brown), Oakley Park, East Grinstead, who included Uxbridge Pink, In Memoriam, Freda Bedford and Jean Pattison. Viscount Hambleden was second with such sorts as In Memoriam, Sunshine, Monument and W. Turner. Gus Mayer, Esq., was first with six vases of Anemone blooms.

The Pompon varieties were not quite so well shown as in former years, although J. W. Hussey, Esq., Matford Lodge, Exeter, brought his usual pretty first prize six vases of disbudded varieties. Gus Mayer, Esq., was second.

Single Chrysanthemums, in the open classes, were shown in great excellence by Mrs. Yarrow (gr. Mr. A. Robertson), Abbey Road, St. John's Wood, London, who was first with nine vases and with six vases of large Singles of superb quality. In the class for nine varieties, Mrs. Yarrow's exhibit included Isobel Felton, Fusilier, Mrs. J. Palmer, W. Knight, Rona, Rita and Kitchener. H. E. Miller, Esq. (gr. Mr. J. Cheer), Red Gables, Purley, was second, showing Golden Seal, Molly Godfrey and Frank Brice. Mrs. Guthrie (gr. Mr. T. Burr), East Haddon Hall, Northampton, was third. The large Singles so magnificently shown by Mrs. Yarrow in the class for six varieties were Rita, Audrey, Fusilier, W. Knight, Rona and Mrs. J. Palmer. Mrs. Brousson (gr. Mr. A.

Wakeling), Newton House, Hampstead, showed, in a second prize collection, Supreme, Molly Godfrey and Mrs. J. Palmer. Viscount Hambleden was third. Lady Juliet Duff was first with a beautiful vase of mixed small-flowered Singles.

The three exhibits from Affiliated Societies were of particularly good quality and illustrated the values of the different types of the flower. The first prize was won by the Finchley Chrysanthemum Society (Secretary, Mr. H. A. Wenden). The large-flowered type was well represented by magnificent blooms of W. Rigby, Mrs. Gilbert Drabble, Julia and Mrs. Algernon Davis; while the vases of Singles, Decorative and Anemones were equally meritorious. The Croydon Horticultural Society (Secretary Mr. T. Aley) was second, and the good large exhibition varieties included H. E. Converse, W. Rigby, R. C. Pulling, Red Majestic and Mrs. Gilbert Drabble.

The two Decorative groups of Chrysanthemums with foliage plants, arranged on the floor, were totally distinct in style of arrangement, but both attracted much attention. The first prize was won by Gus Mayer, Esq. (gr. Mr. R. Cottam), Whistler's Wood, Woldingham, with a very graceful display in which the well-grown Codiaeums (Crotons) and various greenhouse Ferns were of considerable artistic value. E. H. Meyerstein, Esq. (gr. Mr. W. Clapham), Morant Court, Sevenoaks, was awarded the second prize for a group which included many admirable blooms.

OPEN CLASSES.

The most important competition in this section was for the George Monro Challenge Cup, for the best twelve vases of large, Single Chrysanmums, distinct. There were five collections staged, and the trophy was deservedly awarded to Mrs. Yarrow (gr. Mr. A. Robertson), Abbey Road, St. John's Wood, for a grand set. Her varieties were Molly Godfrey, W. J. Palmer, Susan, Rita, W. Knight, Reginald Godfrey, Robert Collins, Rona, Fusilier, Bronze Molly, Sportsman and Isobel Felton. Mr. H. Woolman was second, and his best were Yellow Stewart Smith, Lady Aileen, Golden Seal and Susan. Third, E. Martin-Smith, Esq. (gr. Mr. G. J. Miller), Codicote Lodge, Hitchin.

There was only one exhibit in the class for a display of cut Decorative Chrysanthemums, and this was by Gus Mayer, Esq., who was awarded second prize.

Gus Mayer, Esq., was first for six vases of Anemone Singles, showing Bronze Thora, Mabel Weston, white; Ceres, yellow; Thora, deep rose; Aphrodite, lavender-pink; and Godfrey's Perfection, pale flesh; while in the class for six vases of large Singles, distinct, Mrs. Yarrow was again successful, with especially magnificent blooms of Crimson Dawn, Rita, Mrs. Edith Smith and Mrs. J. Palmer; second, Lady Vansittart Neale (gr. Mr. W. McCaul), Bisham Abbey, Marlow; third, S. Wallrock, Esq. (gr. Mr. W. Holloway), The Manor House, Stanmore.

There were eight entries in the class for three vases of large Singles, distinct, the first prize winner being Mrs. Guthrie (gr. Mr. P. Burr), East Haddon Hall, Northampton, with grand blooms of Golden Seal, Susan and Lady Dymond. The Dowager Lady Annaly was second; and E. Robson, Esq. (gr. Mr. H. Jones), Avenue Road, Regent's Park, third. C. M. S. Sangster, Esq. (gr. Mr C. E. Fear), Green Lodge, Kew Road, Weston-super-Mare, showed the best specimen Chrysanthemum —a grand floriferous plant of Mrs. R. Luxford; second, Lady Juliet Duff (gr. Mr. H. Weaver), Combe Court, Kingston, with a good specimen of Viscount Chinda.

AMATEURS' CLASSES.

Many grand blooms were shown in these classes, in the majority of which competition was keen.

For twelve Japanese blooms, distinct, Mr. George Curran, Sycamore Inn, Nottingham, was first with an excellent set, in which Lady Talbot, General Petain, Mrs. R. C. Pulling and Princess Mary were outstanding; second, Mr. B. Carpenter, 58, Elm Park Road, Finchley, whose best were W. Rigby, Miss Ada Ellis and Marjorie Woolman; Mr. W. Staley Gosport, Hampshire, showed the leading set of six Japanese blooms, distinct, his varieties being Mrs. G. Drabble, Mrs. B. Carpenter, Boule d'Or, Cissie Brunton, Majestic and Yellow Majestic; Mr. George Curran was a close second, and the third prize was awarded to Mr. W. E. S. Debenham, Wimbledon.

John Rowlett, Esq. (gr. Mr. H. Hammond), Gwynnicote, Sanderstead, Surrey, well deserved the first prize for his set of Incurved blooms, for he had grand examples of Romance, Ondine, Progress (two), and Mr. G. Denyer (two), and Mr. G. Curran was again a close second, his best being Romance and Captain Kettle.

Mr. G. Curran was first for three vases of Japanese blooms, again showing grand specimens; second, Mr. A. Pettengell, who secured the first prize for six vases of Singles, with Mr. S. W. Wickens a close second, his blooms of Susan and Cleopatra being exceptionally good.

This latter exhibitor was deservedly first in the class for twelve Japanese blooms, not fewer than eight varieties, his sorts being Mrs. A. Holden, Yellow Majestic, Miss Ada Ellis, Queen Mary, Mrs. E. H. Pearce, Majestic, R. C. Pulling, Princess Mary, Julia (two), C. Davis and B. Carpenter. Mr. G. Curran was second, and Mr. E. A. Crick, third. In the next class, for six Japanese blooms, distinct, Mr. B. Carpenter was first with splendid blooms of Victory, W. Rigby, Miss Ada Ellis, Mrs. A. Holden, C. Davis and Mrs. Algernon Davis; second, Mr. E. J. Elms, Byfleet; third, Mr. E. R. Crick.

Mr. G. Curran was the leading exhibitor of six Incurved blooms (Section B), with Mr. S. W. Wickens, second, and Mr. H. Bull, third; while for three Japanese blooms, the first prize was awarded to Mr. W. E. S. Debenham, with Mr. G. Curran second. Mr. S. W. Wickens showed the best three vases of Singles.

DECORATIVE CLASSES.

The many dinner table decorations of Chrysanthemums were mostly daintily arranged and very effective. The first prize was won by Gus Mayer, Esq., with a graceful arrangement of small-flowered Singles and autumn foliage. Mr. T. Clark, South Chingford, was second, with small, yellow Singles and foliage; and C. M. S. Sangster, Esq., Green Lodge, Weston-super-Mare, was third. The baskets of Chrysanthemums with appropriate foliage were exceedingly artistic. The first prize was won by Mrs. T. Clark, and Mrs. C. Pearson was a good second. In the class for an arrangement of Chrysanthemum blooms suitable for a hall table or sideboard, Gus Mayer, Esq. was first with a good arrangement in a large copper bowl, and he also had the best large vase of Chrysanthemums. Mr. George Curran, was first in the class for a vase of five blooms of Japanese varieties; and S. J. Kirby, Esq., Hatch End, was second. H. E. Miller, Esq., had the best vase of large Single Chrysanthemums, and Gus Mayer, Esq., was first in the class for Singles arranged for effect.

NON-COMPETITIVE EXHIBITS.

These contributed greatly to the success and general attractiveness of the show, for they were arranged around the walls of the hall and several magnificent collections were set up.

Messrs. H. J. Jones, Ltd., staged a spectacular group which included grand blooms of many Japanese sorts, together with Incurved, large Single, and Decorative varieties. Good Japanese Chrysanthemums were W. Rigby, primrose; Mrs. G. Drabble, white, very fine; Miss Ada Ellis, pink; Daily Sketch, Edith Cavell, and others, and these were arranged in large sheaves as a background to the group. Monument, Captain Kettle and Percy A. Dove were outstanding among Incurved sorts, while their large Single Chrysanthemums, in grand condition, included Golden Seal, Susan, Molly Godfrey, Rose Molly, Mary Edwards and Mrs. Joyce Moore. This firm also showed an interesting set of Pompon varieties, notable among which were Gold Climax, Firebird, Mr. W. Sabey, Ethel, White Doty and Lilian Doty. The whole exhibit was well arranged, and the blooms were of grand quality.

Next to this exhibit was another extensive group set up by the King's Acre Nurseries. At the back they had huge sheaves of such Japanese sorts as Yellow Majestic, Mauretania, Mrs. H. Wells, Red Majestic, Mrs. R. C. Pulling, Birmingham and Belle Chinoise, with large vases of these and other sorts dotted throughout the group. The best Single varieties included Enid, rich orange-bronze; Yellow Stewart Smith; Daphne, pink; Phyllis Cooper, palest primrose; J. H. Blyth and White Model, while several good Decorative sorts were also shown in this group.

At the far end of the hall Messrs. Keith Luxford and Co., Ltd., had a splendid group of numerous varieties. In the background were handsome pillars of Japanese Chrysanthemums, notable among which were Miss D. L. Athron, Mrs. R. C. Pulling, T. W. Pockett, Thalia and Birmingham; while forming a bank beneath these were numerous Incurved and Single varieties, broken here and there with vases of Japanese sorts. Among Incurved varieties we noted Romance, rich yellow; Mrs. S. Dove, light pink; Tiger, golden-yellow; Queen of the Pinks, Golden Glory, Progress and Alice Honour, while the best of the Singles were the glorious Kirkland's Crimson, Lady Sanders, a fine yellow; Mrs. F. Brill, deep rose; Catriona, Sonia, rich pink; Absolute, orange-scarlet; Winsome, with dainty, star-like, light crimson blooms, and Nona, white.

In the large group set up by Messrs. W. Wells and Co. Japanese sorts included Charles Davis, Yellow Davis, Princess Mary, Lady Edward Miller, W. Turner, Mrs. C. G. Kelly, Mrs. A. Davis and Mrs. Keith Luxford; while the best of the Single varieties were Jessica, Westhall Gem, Golden Seal, Golden Absolute, Juno and Supreme. The best of the Decorative sorts were Red Jean Pattison, Mrs. Fieldwick, Mrs. R. F. Felton, and Golden Marvel; they also showed Incurved and Pompon varieties of merit.

One of the most striking groups in the hall was that arranged by Mr. A. G. Vinten, who showed Decorative and Single sorts chiefly, in good condition and richly coloured. Striking among the former were Golden Marvel, Yellow Marvel, Golden Glory, Golden Wonder, Shirley Scarlet, Merrivale and Balcombe Pink, while good Single sorts were Jessica, G. Fox Wilson, Daphne, Golden Seal, J. H. Blyth, Phyllis Cooper, very fine, and Exmouth Pink. He also showed several small-flowered Incurved sorts, notably Alice Honour, Ivy Gay, Ra, Progress and H. W. Thorp. Messrs. Cole and Son staged a small group of Chrysanthemums of various types.

Mr. H. Woolman set up a group next to that arranged by Messrs. Keith Luxford and Co. It formed a tall bank, with good blooms of Japanese varieties at the back; among these we noted Mr. T. Slack, Thalia, Lancashire, Iris Cross, Birmingham, Queen Mary and Daily Sketch. Good Single sorts in this group were Mrs. A. Graham, Raleigh, Exmouth Pink, Yellow Prince, Golden Seal and Everlasting. Sultan, Flame and Mayford Cream were choice Decorative varieties.

An extensive collection of later varieties o early-flowering Chrysanthemums from the N.C.S. trials was staged by Mr. W. Hatch, Cookham, Berkshire, and showed the value of these for providing blooms for cutting over a long season in gardens where no glass is available, and with only light protection.

Mr. W. Yandell set up a collection of hardy Decorative sorts, his best being Amorel, F. J. Woods, Brightness, Red Almirante and Cranford Yellow. Mr. L. Mills arranged a handsome group of superb Decorative Chrysanthemums in pots. There were masses of Jean Pattison, Caprice du Printemps, Tapis d'Or, Kathleen Thompson, Uxbridge Pink, Blanche du Poitou, and Rose Chocod. He had large ornamental baskets of Jean Pattison, Uxbridge Bronze and Dorothy Wilson at the back, with mounds of R. C. Pulling, Liverpool and others between them.

SOCIÉTÉ NATIONALE D'HORTICULTURE DE FRANCE.

The Autumn Exhibition of the French National Horticultural Society was held from October 25 to November 3 at the usual riverside rendezvous, Cours-la-Reine. Chrysanthemums and Dahlias—the latter being especially numerous owing to the mild weather—held pride of place, but fruits were also plentiful and well varied.

Chrysanthemums.

The firm of Vilmorin-Andrieux et Cie, whose exhibit was non-competitive, had, as usual, a very fine display of Chrysanthemums. As in former years, the decoration was of classic style, the magnificent group, with a hollow centre, occupying the whole central portion of the marquee, with pot plants trained in various ways, and faultless specimens in pyramids, cones, etc., or with single blooms. Among others were noted André Bruhier, pink; Marie Dufour, white; Oubanghi, yellow; Cettois, pink; Hurepois, yellow; as border plants Rufisque, pinkish-white; Purpurine, purple, and Gerbe d'Or, yellow; with Blanche Poitevine and Aviateur Cornu, both market plants which are very popular in France. The certificated novelties of the firm are mentioned below.

Madame Veuve Martin, of Champigny, sent a very fine display, excellently arranged, composed of recent varieties including Lutèce, pink; Beau Soleil, a very fine bright yellow; Viola, violet with paler reverse; Souvenir de G. Péchou, old rose, chamois reverse; and Madame P. Féron, garnet-red.

M. Laumonnier-Férard, of Paris, had a massive group at the end of the marquee, composed solely of Single varieties, which made a fine splash of colour. Among the varieties noted were Havrais, pink; Marocain, brownish-yellow; Caennais, pink; Orléanais, yellow; and Miromesnil, white.

From M. Lochot, of Orsay, there was a pretty group containing the now well-known varieties Ville de Strasbourg, pink, and Chrysanthémiste Lochot, with Madame Joseph Raimbaud, a yellow sport from Ami Paul l'Abbé which, when first flowering, seems preferable to R. C. Pulling. There was also a collection of Singles, known as Gerbera-flowered, or Anthemis-flowered, including Marinette, ochreous-red; Pierrette, chrome-yellow; and Yvette, old rose, charming little flowers, almost hardy, of which several were very fragrant. M. Vialette, of St. Germain-en-Laye, sent a very beautiful exhibit of cut flowers, including Belle Aunisienne, pure white with large rays; l'Albigeois, deep mauve, with pink reverse; Madame Lhuile, carmine and lilac; Madame Charlot, milk-white; Majestic, brownish-yellow; and Rose Day, pink.

A large collection of plants in pots was exhibited by M. Charrier, of Tours, including Petite Marie, white; Maréchal Foch, pink; Tooben, pink; Le Phare, pinkish-white with pointed florets; and Yvonne Clément, yellow, with a greenish centre. M. Morin, of La Rochelle, showed Colombine, white; Hermine, yellowish-white; Madeleine Morin, yellowish; De Cheverny, pink, with curled petals; and Candeur Rochefortaise, feathery, white.

A very beautiful display of cut flowers was furnished by M. Laine, of Igny, including Maurice Lhuile, yellow; Admiral Beatty, white; Deuil de Paul l'Abbé, pink with silvered reverse; Philippe Rivoire, and Ami Paul l'Abbé. From M. Lemasson, of Limoges, came some fine pot plants, namely Calypso, pink, and Euterpe, red and gold, and as cut flowers, Petit André and Salambo, white, with elongated florets.

M. Fourdrignier sent from his Pierrefitte nurseries, cut flowers of the following varieties:—Mrs. G. Drabble, white; Captain Fox, brown; Deuil de Nungesser, pink with silvered reverse; Robert Bolli, pink incurved, and R. C. Pulling. From the Igny Horticultural College (Principal, M. Vialla) came some very fine cut flowers, including R. C. Pulling, Ami Paul l'Abbé, Captain Fox, Léonie Legrand (white, with green centre), and M. J. Paquin, brownish-yellow. The Paris Municipal Horticultural College, St. Mandé (Professor M. Duvernay), showed two groups of pot plants in the following varieties, among others, Edith Cavell, yellow; Louisa Pockett, white; and Président Millerand.

In the competition for the C. P. Cup, offered for the largest flower in the exhibition, M. Fourdrignier, with the variety Ville de Strasbourg (pink), tied with M. Laveau, who showed H. E. Converse, a yellow incurved variety; and the second place was won by M. Féron, for the variety Souvenir de G. Péchou, old gold. Some cut flowers of Ville de Strasbourg, which were still looking very fresh, were stated to have been cut three weeks previously.

As usual, the Committee appointed to award Certificates of Merit to novelties was exceedingly generous, too much so, in our opinion, for no fewer than forty-three Certificates were issued! Among the finest of these varieties were Cochinchinois, Incurved, pink and silver; Algérien, pink, tinged with chamois; and Marocain, deep red, with gold reverse; these three shown by the firm of Vilmorin. Souvenir de Louis Lemaire, pink and white; Dr. Desmaroux, red and gold; and Neige d'Octobre, pure white; exhibited by M. Lochot, Orsay. Jeanne Carlisle, red, with paler reverse; Lisieux, pale pink, white centre, long florets; and Côte d'Or, a very fine yellow; shown by Madame Vve. Martin, of Champigny. Madame Oscar Dahl, pure white; Mdlle. Simone Decault, pink; Neige Rochellaise, white; and Chrysanthémiste Buisson-Metra, reddish-brown, all exhibited by M. Morin, of La Rochelle, the two last-named varieties as market plants. Finally, may be cited three varieties presented by M. Lemasson, of Limoges, namely, Madame G. Romet, an Incurved pink variety, with paler reverse; Ami Lepeu, red and gold, and Frégoli, red, with the florets paler on the reverse side.

Dahlias.

The absence of early frosts enabled a number of fine groups of Dahlias to be exhibited. MM. Cayeux et Le Clerc, of Paris, who are well-known specialists, made an excellent display, comprising not only Dahlias of their own raising, but most of the more recent varieties from all sources. Among others were included Président Fernand David, a red Cactus variety, golden, with yellow centre; Flamboyant, cardinal-red, with gold reverse; Rosalie Defrance, a beautifully erect carmine flower; and Rapsodie, pink. Among the varieties known as "Decorative" were to be noted Autumn Gem, salmon; Rosenkönigin, pink; Fournaise, orange-yellow; and Loïe Fuller, a curious brownish-yellow and gold colour. Among American varieties were Jessie Prescott, orange; John Lewis Childs, a peculiar streaked red and yellow variety; Faith Garibaldi, pink; Marmion, yellow; and Trentonian, coppery.

The firm of Vilmorin also showed a considerable collection, arranged in white baskets, including Amun Ra, yellow, shaded with red; de Schelde, red; Jongleur, mauve; Calcutta, flesh-pink; Ramire, red; Polar Bear, pure white; Mellila, mauve; Arizona, shrimp-pink; and Macao, yellow. From M. Romageon, of Saint Prix, a nice group was sent comprising, among other varieties, Sphinx, brownish-yellow; Spartacus, deep red; Démoniaque, also deep red; Cocorico, red, and King Harold, red; and Pride of San Francisco, blood-red.

M. Reboux, of Montigny les Cormeilles, showed Vanité, pinkish-yellow; Nagels Roem, yellowish-cream; Insulinde, yellow; and M. J. Waterken, deep red; while from M. G. Truffaut, Versailles, came Wizard of Oz, pink; Bordeaux, red; and Siskijou, a variety with enormous blooms, pink in colour but yellow at the base of the florets. M. Thiébaut, of Paris, contributed Rheinische Mädel, a curious pink Cactus variety, with white tips.

Several novelties were certificated by the Floral Committee, and Certificates of Merit were awarded to Chasteté, pure white, and Ehrenpreiss, a pretty pink Cactus variety, shown by MM. Cayeux et Le Clerc; Charivari, a fine magenta-red variety presented by M. Romageon; and Elisa Clark Bull, a beautiful American Decorative white Dahlia, shown by M. Thiébaut.

Various.

The two beautiful groups of tuberous Begonias, which can always be relied upon, from MM. Vallerand Frères, of Taverny and Asnières, and M. Billard, of Vésinet, respectively, were displayed. The first-named firm had set up their exhibit as a border in which the different varieties were planted in triangles of colour, clearly separated by narrow bands of turf; the second had formed a round group, in which the varieties were shown in sections according to colour, the effect being extremely gay. Among the tuberous Begonias noted, which included both single and double sorts, and comprised many different colours, such as pink, salmon, white, orange, copper-colour, etc., were B. cristata, pink (very fine), Guillaume Eysser (red), and Souvenir de Guynemer (double, pink).

There were two exhibits of Roses, still very beautiful in spite of the advanced season, brought by M. Leveque, of Ivry, and M. Defresne, of Vitry, respectively; in the display of the first-named firm were several recent varieties, including Director Rubio, magenta-red; Jules Gaujard (Pernetiana), red; Madame Henri Queuille (Pernetiana), shrimp-red; Maréchale Pétain (Hybrid Tea), cochineal-red; and Li Bures (Pernetiana), red and yellow.

The collective exhibit of the Paris district nurserymen's syndicate is worthy of special mention; the products were of very fine quality, varied, and effectively arranged, and each separate exhibit bore, ih addition, the name of the variety, that of the individual exhibitor. Besides Chrysanthemums and Dahlias there were some very fine Kentia Palms and foliage plants; various Ferns; Adiantum concinum; a vigorous specimen of Alsophylla splendens; and Nephrolepis President Roosevelt; also Heaths, some fine Lilies, white Lilac, and sheaves of Gladioli.

M. Thiébaut, of Paris, showed a beautiful collection of Cacti and various succulent plants, making a very pretty ensemble arranged in small specimens on a ground-work of pink sand; these plants appear to be becoming popular again in France. Among the specimens shown were Pilocereus senilis, Cephalocactus Hoppenstedtii, Echinocactus Grussonii, Ferocactus latispinus, and Cereus perluscens with a bluish stem.

M. Weiss, of St. Cloud, showed, by means of a decorative and very artistic display in the modern style, how to utilise Cacti and other succulent plants in attractive rectangular vases in tones of white and pink on a silver ground, against a wide red background. Echinocactus, Opuntias, Aloes, and Mesembryanthemums, were effectively arranged. M. Weiss also showed a small rock garden, with various alpine plants, and his usual series of little "Japanese" garden scenes in miniature, with tiny trees and alpines. Similar exhibits were shown by MM. Posmoury, of Colombes, and Kolb, of Meudon.

M. Charlot, the Paris florist, had composed an immense sheaf, very lightly arranged, in the centre of a bowl, with long, pendant branches decorated with blue Vandas, yellow Oncidiums, and pink Cattleyas—these being the only Orchids in the exhibition. M. Dijon, another Paris florist, brought some very pretty little miniature table decorations representing tiny gardens.

Fruits.

The exhibits of fruits were very numerous and of excellent quality. M. Nomblot-Bruneau, of Bourg-la-Reine, brought a fine collection of Pears and Apples, among which, besides the better-known varieties, there were some less common, such as Apples Fenouillet, red; Reinette des Carmes, red; Reinette Dorée, Api Noir, and Titowka, pretty red fruits with streaks.

From the National College of Horticulture at Versailles (Principal, M. Pinelle), there were some very fine specimens of commercial fruits, such as Pears Charles Ernest, Passe-Crassane, Duchesse d'Angoulême, Beurré Diel and Doyenné du Comice; Apples Calville, Reinette du Canada and Peasgood's Nonesuch. There were also good specimens of streaked Beurré Gris and

Doyenné du Comice, and of the Apple Bismarck, a very good red colour. The firms of MOSER, Versailles, and CROUX, of Chatenay, also sent important exhibits of Pears and Apples, in which were noted Pears Duchesse Bérard, enormous fruits and very brown; Madame Bellet, a pretty colour; Alexandrine Douillard, and Merveille Ribet; and of Apples, Hower, a fine red; Maiden's Blush; de Grignon, and Saint Laurence, well-coloured.

M. DUPOIRIER, of Quincy-Ségy, sent fine specimens of Apples Belle Joséphine and Chataignier, and an enormous Pear, Virginie Baltet. M. SALOMON, of Thomery, had fruits of Doyenné du Comice and Passe-Crassane, of an average weight of 600 grammes. M. GAUTILLOT, of Montreuil, showed Apples Reinette du Canada, Api Rose, Emperor Alexander, and Belle du Hâvre, decorated with vignettes; and Peaches Salway and Belle Impériale.

In the collective exhibit of the students of the Arboricultural Course at the LUXEMBOURG GARDENS (Professor M. Cuny), there were some perfect specimens of Doyenné du Comice Pears; Calville Blanc and Canada Gris Apples were also excellently shown. Very fine exhibits of commercial fruits were sent by the IGNY HORTICULTURAL COLLEGE (Principal, M. Vialla), and by M. LAMBERT, of Soissons.

Grapes were well shown by M. Parent, of Rueil, by M. SALOMON, of Thomery, and also by the THOMERY VINE GROWERS' SYNDICATE. Among the black Grapes shown were Alicante and Black Muscat; Foster's Seedling, Général Galliéni, Gradiska, and Angelino.

There was one bunch of Balafant (white) weighing two kilos. The curious variety Kadin Bapmak was noted, with white, pointed, elongated berries; and the perfect bunches of Chasselas doré de Fontainebleau shown by the THOMERY VINE-GROWERS' SYNDICATE were well worthy of mention.

M. CHAPRON, of Caen, showed pot plants laden with fruits, including the best varieties of Strawberries, such as Saint-Fiacre, Général de Castelnau, Abondance, etc., and a new variety, Madame Raymond Poincaré, with brightly coloured fruits.

There were some very fine exhibits of vegetables, notably that of Messrs. VILMORIN-ANDRIEUX ET CIE., always so complete and decorative. The IGNY HORTICULTURAL COLLEGE also showed vegetables, including some red Malaga Batatas of enormous size. M. JOALLAND, of Nantes, showed a large collection of Potatos comprising 210 varieties.

TREES AND SHRUBS.

The usual firms showed trained fruit trees, namely, MM. NOMBLOT-BRUNEAU, of Bourg-la-Reine; CROUX, of Chatenay; MOSER, of Versailles; and ALAVOINE ET SOULIER, of Jouy-en-Josas. Trees were shown in palmettes, vases, cylinders and pyramids; there were Pear and Apple palmettes in nine stages, and many other wonderful specimens of the art of training and grafting.

There were excellent exhibits of ornamental trees and shrubs from MM. ALAVOINE ET SOULIER, of Jouy-en-Josas; MARTIN LECOINTE, of Louveciennes; LÉCOLIER, of La Celle-Saint-Cloud; THUILLEAUX, also of La Celle-Saint-Cloud; and LIÈVRE, of Vitry. Some fine examples noted were of Ligustrum elegantissimum var. aureum, Thuyopsis dolabrata var. variegata, Cedrus Deodara var. robusta (weeping); Euonymus radicans var. Silver Gem, Sequoia gigantea var. pendula, and Ilex nigricans var. marginata aurea.

M. DUFAY, of Chevry-Cossigny, sent a pretty collection of Osiers and Poplars, saplings of Salix vitellina (yellow wood), Salix fragilis (brown wood), and S. viminalis (green wood), with photographs of the plantations and showing the basket-makers' methods.

As usual, in the section for sundries a great number of exhibitors were showing their goods, representing almost all the materials and tools used in horticulture.

The First Class Grand Prix d'Honneur of the President of the Republic was awarded to the firm of CROUX ET FILS, for their exhibit as a whole (fruits, fruit trees and ornamental trees and shrubs). The second Grand Prix was won by MADAME VEUVE MARTIN, for Chrysanthemums.

Coinciding with the Exhibition, a National Fruit Congress for France and her colonies was held at the offices of the Society in the Rue de Grenelle. A number of papers were read and discussed, but the main subject was the commercial utilisation of fruits, and their manufacture into jam. There were various activities connected with the Congress, among others a costume dance, in which the guests represented various attributes of flowers and fruits. *A. M.*

BRIGHTON AND HOVE HORTICULTURAL.

THE Autumn Show of this Society, held in the Dome and Corn Exchange, Brighton, on November 12, 13 and 14, was a great success, and it is very apparent that if this show continues to increase in popularity, fresh accommodation will have to be found for it. All the competitive classes, and especially those for Chrysanthemums, were well filled, and there were numerous trade exhibits, which were not, however, up to last year's standard; the general management of the show was excellent, and a high standard of quality maintained throughout.

COMPETITIVE EXHIBITS.

The show is primarily for Chrysanthemums, and these, naturally, were the chief feature. There were several grand exhibits in the important open class for an oval group of Chrysanthemum plants, the best being that staged by W. H. VOKINS, Esq. (gr. Mr. W. J. Scott), Beechwood, Withdean, who had a grand mound of excellent Japanese sorts; second, Councillor E. E. LYONS (gr. Mr. D. Pidgley), Withdean, Brighton.

ANNIE VISCOUNTESS COWDRAY (gr. Mr. R. Middleton), Paddockhurst, Crawley, was a good first for twenty-four Japanese Chrysanthemums, not fewer than eighteen varieties, R. C. Pulling, Red Majestic, Yellow Majestic and Mr. G. Drabble being her outstanding sorts; the second prize was awarded to Sir W. CHAMPION (gr. Mr. R. W. Wheare), Danny Park, Hurstpierpoint, who also had a very good collection.

EARL BEATTY, Reigate Priory, Reigate, led for twelve Japanese blooms, distinct, his blooms of Louisa Pockett, Yellow Majestic and Queen Mary being the cream of the collection; second, S. SCULLY, Esq. (gr. Mr. T. Elder), Old Place, Lindfield; while for six Japanese Chrysanthemums, distinct, Dr. E. MALTBY, Brighton, was first, and EARL BEATTY, second. The first prize for three vases of Chrysanthemums, distinct, was won by S. SCULLY, Esq., who showed splendid blooms of W. Rigby, General Pétain and Mrs. G. Drabble, with ANNIE VISCOUNTESS COWDRAY a close second; while in the class for three Incurved Chrysanthemums, Mr. B. RUBENSTEIN, Timbers, Rustington, led with Advance, Calypso and Percy A. Dove; second, Mr. C. LUCKIN, Wadlands, East Grinstead. W. S. POOLE, Esq. (gr. Mr. J. G. Casewell), Oakwood, Haywards Heath, was first for six vases of Single Chrysanthemums, showing Red Molly, Susan, Miss J. Wisby, Mrs. J. Palmer, Bronze Molly and Molly Godfrey; with ANNIE COUNTESS COWDRAY second. W. S. POOLE, Esq., staged the first prize collection of twelve disbudded Single varieties, while in the very popular class for four vases of Decorative or Incurved blooms, Mr. C. S. JOHNSON, Worthing, was deservedly first; and ANNIE VISCOUNTESS COWDRAY, second.

There were four good exhibits in the class for six bush Chrysanthemums, those shown by Mrs. GIBBS (gr. Mr. E. Norris), Fairmile, Haywards Heath, being adjudged the best, for they were magnificently grown plants; Councillor E. E. LYONS was a good second.

In the section open only to amateurs and allotment holders, the most important floral class was for a circular group of Chrysanthemum plants, seven feet in diameter, and the exhibits in this class were quite a feature of the show. Mr. R. MOORE, 18, Sun Street, Lewes, was first, with a very effectively arranged group, and the second prize was awarded to Mr. N. D. BROOKE, Hove. Mr. C. LUCKIN was first for three vases of Single Chrysanthemums in this section, and he also secured the premier award for one vase of twelve distinct Single Chrysanthemums; Mr. G. RUNNELL, Brighton, was second in this class.

The decorative classes were, as usual, very popular, and several tastefully executed designs were noted. CECIL T. CHANDLERS, Esq. (gr. Mr. F. W. Chilvers), Sherrington Manor, Selmston, had the best table of Carnations, his blooms being of excellent quality and artistically arranged; second, S. SCULLY, Esq.

There were six entries in the open class for a decorated dinner table, and that arranged by Miss M. WOOLVEN, Wadlands, East Grinstead, consisting of scarlet Carnations, Madame Butterfly Roses and Lily-of-the-Valley, was awarded the first prize; while in the similar class in the ladies' section, Chrysanthemums only allowed, Miss J. EVERSHED, Betchworth, Surrey, was awarded the first prize for a charming arrangement of crimson and bronze Single sorts.

The classes for fruits were, in general, well filled and high quality was evidenced. Several excellent bunches of Grapes were staged in the two classes allocated to these, Mr. H. T. C. PEPPER, Salsington Letts Vineries, Worthing, being first for two bunches of black Grapes, showing Gros Colmar in excellent condition, and Lieut.-Col. P. R. PAPPILLON (gr. Mr. E. Carpenter), Crowhurst Park, Battle, first for two bunches of white Grapes, with grand bunches of Muscat of Alexandria.

Sir W. CHAMPION showed the best basket of twelve fruits of a culinary Apple, his variety being Newton Wonder; second, Mr. C. S. JOHNSON; and Sir W. CHAMPION also led for four dishes of dessert Apples, with Mr. A. O. COSHAM, Park Avenue, Upper Willingdon, a close second. Messrs. SHEPHERD AND HYSLOP (gr. Mr. T. A. Sandalls), Rottingdean School, Brighton, showed the best four dishes of culinary Apples, distinct; second, Mr. A. H. PARSONS, Lewes; while in the classes for two dishes of dessert, and two of culinary Apples, respectively, Mr. C. S. JOHNSON and the EARL OF CHICHESTER (gr. Mr. A. Mason), Stanmer Park, were successful.

Mr. A. O. COSHAM showed the leading two dishes of dessert Pears; Mr. A. H. PARSONS led for one dish of stewing Pears; W. J. YAPP, Esq., was first for two dishes of Apples and two of Pears, showing Cox's Orange Pippin and American Mother Apples, and Pitmaston Duchess and Doyenné du Comice Pears; and J. H. MARTIN, Esq., showed the best set of three dishes of Apples and three of Pears, his varieties being, Apples King of Tompkins County, Hollandbury and Bramley's Seedling; and Pears Beurré Alexander Lucas, Pitmaston Duchess and Doyenné du Comice.

There were numerous classes for vegetables, those in which special prizes were offered by seedsmen being especially popular. The Onions and Potatos were of very good quality, and there were several notable exhibits in the classes for collections of vegetables. In the special class for a collection of nine distinct vegetables, open to amateurs and allotment holders in the county of Sussex, Mr. R. MOORE, Lewes, was a good first.

The affiliated allotment societies' competition was a feature of the vegetable section. A collection of twelve varieties of vegetables was required and four exhibits were staged, the first prize being secured by the HOVE HORTICULTURAL AND ALLOTMENT HOLDERS' ASSOCIATION, and the second prize by the ALLEN WEST GARDENERS' AND ALLOTMENT HOLDERS' ASSOCIATION, both showing produce of good quality.

NON-COMPETITIVE EXHIBITS.

These were not so numerous as usual, but they assisted in making the show a success.

Very attractive exhibits of Chrysanthemums were staged by Mr. A. G. VINTEN, who showed many Decorative and Single sorts in splendid condition, and brightly coloured; and by Messrs. Keith Luxford and Co., Ltd., who made a special feature of Japanese sorts.

Collections of Apples were arranged by the Barnham Nurseries, Ltd., and Messrs. J. Cheal and Sons, Ltd. Mr. W. G. Bright had a miscellaneous collection of flowering and foliage subjects; Mr. F. Woollard had fruiting and flowering subjects, together with several dishes of excellent Apples; and Mr. Arthur Pratt showed Ferns and Chrysanthemums.

Cyclamens in pots, with various Ferns, were shown by Messrs. W. Miles and Co., Ltd.; Mr. C. J. Tugwell had a miniature garden; and Mr. H. Anscombe had an attractive group of Cyclamens, Begonias of the Gloire de Lorraine type, and Chrysanthemums.

Messrs. Allwood Bros. set up a small group of perpetual-flowring Carnations, and Mr. H. Hemsley had an interesting collection of shrubs and Conifers, and a miniature rock garden; he also showed baskets of excellent Apples.

Messrs. W. Balchin and Sons, Ltd., had a spectacular florist's display, and the decoration of the orchestra dais was tastefully filled by the Brighton Corporation (Supt. Mr. McLaren), Chrysanthemums in variety being used for this purpose.

There was only one trade exhibit of vegetables and this was a very excellent one by the Premier Seed Co., Ltd., who showed a wide variety of excellently-grown produce.

PROFESSIONAL GARDENERS'.

This Society held a meeting in the new Horticultural Hall Lecture Room on November 7. Mr. MacCormack, President, took the chair, and set forth the objects of the Society, and urged the necessity of unity among gardeners. Mr. G. Reid, General Secretary, Pollard Hall, Gomersal, and Mr. Jones, Harrogate, supported the President, who then invited questions, and after a good discussion, a proposition was carried that a branch of the Association be formed in London. Mr. A. M. Hope, Enfield, Middlesex, undertook to act as Secretary, *pro. tem.*, and will arrange for another meeting in the near future.

READING GARDENERS'.

There was an excellent attendance of members of this Association at the fortnightly meeting, held in the Abbey Hall, on the evening of November 4, and presided over by the Chairman, Mr. W. Broomfield.

The feature of the meeting was the floral competitions, the arrangements of the flowers having to be made in the room before the members. Twenty minutes were allowed for each bowl to be made up. The judges made their awards as follows:—

For a bowl of Chrysanthemums arranged for effect, own foliage, eight entries, first, Mr. A. W. Gower, Calcot Grange Gardens; second, Mr. A. Manley, Highfield Park Gardens, Heckfield; and third, Mr. C. J. Howlett, The Yews, Earley.

For a bowl of flowers and foliage, berries allowed, arranged for effect, there were seven entries. Mr. J. Wynn, Hammond's Gardens, Checkendon, was first; Mr. E. Blackwell, Foxhill Gardens, Reading, second; and Mr. F. Haines, Calcot Hanger Gardens, third.

In the non-competitive section, Mr. E. Blackwell received a First Class Certificate for a batch of very fine Solanum capsicastrum, the plants carrying healthy foliage and large, well-coloured berries. Mr. C. J. Howlett gained an Award of Merit for three profusely-flowered plants of Chrysanthemums. Mr. C. Moulton, Rookwood Gardens, Shinfield Road, Reading, exhibited a dozen fine Quince fruits; and Mr. F. Turner, Southview, Calcot, showed two vases of white Chrysanthemums.

The lecture arranged for the evening was "Hydrangeas," by Mr. H. Reeves, Broadfield Gardens, Reading, but this had to be postponed until the spring owing to the lateness of the hour at which the competitions finished.

Obituary.

J. A. Best.—East Anglia in particular, and horticulture in general, have suffered a great loss by the death of Mr. J. A. Best, who was employed for over forty years at Easton, near Framlingham, where he served as head gardener for a considerable portion of that period. He was a very successful cultivator and organiser, ever ready to help both amateur and professional gardeners. Courteous and kindly, he possessed a charming personality that attracted many friends and earned for him the deepest respect of his employers and particularly of Lady Mary Hamilton, who spent her girlhood at Easton before she became Duchess of Montrose. One of the old Victorian school of gardeners, Mr. Best excelled as a grower of Grapes and Peaches, hardy fruits, vegetables and Chrysanthemums. The remains were laid to rest at Easton Church amid many tokens of friendship and respect, wreaths being sent by (among others) the Dowager Duchess of Hamilton, the Duke and Duchess of Montrose, and Mr. R. C. Notcutt.

Archibald Chisholm.—We deeply regret to learn that Mr. A. Chisholm, the horticulturist in charge of the Government Provincial Council Gardens in Bloemfontein, South Africa, died suddenly in that city, early on Sunday, October 6, at the age of fifty-nine. He had been in the best of health and spirits on the previous evening, left the bowling greens at 6 p.m., after dinner listened-in to wireless music, and went to bed apparently quite well. He was found dead in bed the following morning. He had expired at about 6 a.m. from heart failure. His sudden death came as a great shock to his wife and son, and to those of his friends who had seen him on the previous day. Mr. Chisholm was born at Berwick, and he served his apprenticeship as horticulturist in his native town. Having passed his examinations in Glasgow, he received an appointment in Nottinghamshire, and was subsequently placed in charge of the gardens on the estate of the Duke of Buccleuch, in Midlothian. The deceased gentleman went out to South Africa under the Scottish Settlers' Scheme subsequent to the Boer War. In 1904 he was appointed to the Government position in Bloemfontein, which he held until his death. Mrs. Chisholm hails from Loch Syne, in the west of Scotland; their son, Noel, has served his apprenticeship in the electricity department of the Bloemfontein Municipality. The funeral took place on the day after death, the service being conducted according to the rites of the Presbyterian Church.

John Harrison.—A typical Victorian business man, tall and courtly, wise far beyond the average, and possessing an unusually wide knowledge of vegetable and agricultural seeds, "John Harrison, of Leicester" has passed away at the great age of eighty-five years. He was a fine man, and we were proud to have enjoyed his friendship for more than a quarter-of-a-century. One of the best known men in the seed trade, Mr. John Harrison, F.L.S., never stooped to anything doubtful in business, and thus he won the deepest regard and highest respect of all engaged in the seed industry. He was President of the Horticultural Trades' Association in 1909, and held many important positions in midland agricultural circles, and until advancing years brought with them the increasing disability of deafness he was a very regular attendant at the meetings of the Royal Horticultural Society, of whose Fruit and Vegetable Committee he was a member for a very long period. Although head of Messrs. J. Harrison and Sons, seedsmen, Leicester, he had of late left the chief conduct of the business in the capable hands of his son, Mr. J. Harrison, junr., under whose care it will continue. A portrait and appreciation of Mr. John Harrison, senior, appeared in *The Gardeners' Chronicle* of March 26, 1921.

Thomas Lloyd.—We learn with regret of the death of Mr. Thomas Lloyd, who passed away in the Manchester Royal Infirmary on November 2, at the age of sixty-eight. For the past two-and-a-half years, Mr. Lloyd had charge of the gardens at The Hermitage, Holme Chapel, Cheshire, the residence of F. Cornall, Esq., and previous to that he was for thirteen years gardener at Belmont Hall, Northwick. Mr. Lloyd also spent six years in the service of the late Sir O. Wakeman, at Yeaton Peverey, Shrewsbury. He leaves a widow, two sons and a daughter to mourn his loss. The elder son is Park Superintendent to the Todmorden Corporation.

John Edward Mason.—His numerous friends in the horticultural world will learn with regret of the death of Mr. John Edward Mason, a director of Messrs. Joseph Bentley, Ltd., the well-known firm of chemical manufacturers, which took place on the 1st instant, at his residence, Barrow House, Barrow-on-Humber, Lincolnshire.

Louis-Joseph Philippot.—We regret to learn of the death of M. Louis-Joseph Philippot, the President of the Administrative Council of the Co-operative Society owning the famous Brussels market known as the Halles des Producteurs. He was a man held in the greatest respect, and had been awarded several orders, including that of Chevalier de l'Ordre de Léopold II, and the Special First Class Medal of Agriculture. He died at La Hulpe on October 29, and his funeral, on the following Saturday, was attended by a large concourse of friends.

ANSWERS TO CORRESPONDENTS.

Hard Tennis Court.—*H. J. J.* We would advise you to commence operations on your proposed tennis court immediately, particularly so if you have decided to make use of the turf from the tennis site by relaying it on some other site. It is also advantageous to prepare the foundations, *i.e.*, excavating, draining (if necessary), bottoming, and consolidate with a heavy roller, at the earliest opportunity, even although the court will not be required for play until April next. By the month of March any weakness in the foundation will have shown itself, which can easily be made up again to the required level, and the court will then be ready to receive the final layer. In preparing the foundation now, provided, of course, the finishing material is properly laid, you will have a court with a perfect playing surface for all time.

Shrubs for Planting near Large Cedar.—*X. Y. Z.* In your enquiry, you omitted to state what space you had to fill, and this information would have proved a help in making a selection. At the back you could plant Pyrus floribunda var. atrosanguinea and Pyrus purpurea, which make, in time, small trees up to twelve or fifteen feet high. If they are too tall for the position, you could try Spiraea ariaefolia (discolor); Buddleia variabilis var. Veitchiana, Philadelphus grandiflora, Lilacs, such as Madame Lemoine, double, white; Marie Legraye, single, white; Souvenir de Louis Späth, single, violet-red; Philemon, single, red; and Charles Joley, double, dark red; also Viburnum Opulus var. flore pleno. For the middle area you could select from the following, viz.:—Viburnum plicatum, Forsythia intermedia var. spectabilis, Buddleia globosa, Magnolia Soulangeana, Philadelphus Virginal, Ribes atrosanguinea, Berberis stenophylla and Rhus Cotinus; while plants suitable for the front lines may be selected from the following:—Magnolia stellata, Berberis Wilsonae, Berberis Thunbergii, Berberis aquifolium, Daphne Mezereum, Hypericum patulum, Hypericum calycinum, Olearia Haastii, Philadelphus Bouquet Blanc, P. Mont Blanc and P. Mére de Glace, Ceanothus Gloire de Versailles, also Lavender and Rosemary; Spiraea Anthony Waterer, S. Thunbergii and Viburnum Carlesii. Regarding the dry border under the Cedar, you ask what class of plant would grow in it. If it is shaded by the Cedar, you must employ plants that will withstand shade, such as Ivy, Berberis aquifolium, Ruscus aculeatus, Hypericum calycinum, Euonymus radicans, and Vinca major and V. minor.

SUPPLEMENT PLATE.

Iris ensata.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the past fifty years at Greenwich, 42·1°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, November 20, 10 a.m. (Greenwich time). Bar. 29·8. Temp. 52°. Weather, Fine.

Intensive Manuring.

Most good gardeners—at all events, those who produce for market—believe in and practise a liberal and judicious use of manure and fertilisers. Nowhere, for example, is better cultivation to be seen than in the Potato-growing districts of England and Scotland, and nowhere, in these islands at least, is there to be found a more liberal and scientific use of fertilisers. Yet in private gardens, although farmyard manure is used not ungrudgingly—where it is to be had—the application of fertilisers is apt often to be sporadic and niggardly. This is true not so much of the larger gardens as of the smaller ones. Therefore, it may be both interesting and instructive to summarise briefly the results of experiments now being carried out by the National Institute of Agricultural Botany in intensive manuring as against ordinary manuring. Needless to state, the experiment which was made on Wheat bears a special interest to farmers, but it also conveys valuable lessons to gardeners. The cost of applying the ordinary dressings of superphosphate, kainit and nitrate of lime amounted to 18s. 6d. per acre in the year 1926-27; the cost of the dressings on the intensively manured areas was 79s. 9d. per acre. In the second year the corresponding figures were 24s. 11d. and 68s. 9d. Evidently, therefore, fertilisers were used liberally in the intensively manured plots. Yet they paid not unhandsomely. In the case of one variety, Yeoman II, the increased yield of grain produced by the intensive treatment was 6·8 cwts. in 1926-27, and 9·2 cwts. in 1927-28, the former year yielding a profit of 12s. per acre, and the latter one of £2 1s. 3d. per acre. In the case of the other variety, Squarehead's Master, used in the experiment, the profit from intensive manuring was less—the average for the two years being 12s. 8d. per acre as against the Yeoman II average of £1 6s. 7d. Naturally enough, the yield of straw was also increased by the intensive manuring, and the value of the increment is set off against the extra cost of applying the fertilisers. Mr. Hawkes, to whose account[*] of the experiments we are indebted, is careful to point out that this is not the whole of the story. The two varieties behaved very differently to intensive manuring. For Squarehead's Master lodged badly in the heavily-manured areas, while Yeoman II stood well. Even more interesting is the observation that whereas intensive manuring did not improve the quality of the grain of Squarehead's Master, it undoubtedly did improve that of Yeoman II. In this part is the moral which we wish to inculcate. Quality matters much—often more even than quantity—to the gardener. To grow varieties the crops of which may be improved quantitatively and qualitatively by intensive manuring must be a profitable procedure. Consider, for example, the Potato. How wide is the difference between a really good Potato—a delicious vegetable—and the ordinary Potato—a rubbishy affair not worth eating. If the shy-bearing, good-flavoured varieties can be made more productive by intensive manuring the sooner it is done the better, for it would increase the pleasures of the table to those who grow their own food, and it would undoubtedly increase consumption of Potatos on the part of the general public. There is a wide and useful field for research here, and we hope that it may soon be intensively cultivated.

Our Supplement Plate.—The distinct and beautiful Iris ensata, the subject of the Supplement Plate we have pleasure in presenting with this issue, is a member of the Apogon section of the genus Iris, and is a widely distributed species, being found in Central Asia, Kashmir, China and Korea. It is a deep-rooting plant, forming a compact, rhizomatous rootstock, and is thus better able to withstand long periods of drought than many Irises, its foliage remaining fresh until cut down by frosts. It has narrow, linear leaves, varying in length from a few inches at flowering time to eighteen inches to two feet when fully developed. Its flower stems vary from two inches to about twelve inches high and bear single, terminal flowers which vary in colour from pure white, lightly veined with green, to dark blue- or reddish-purple, with the standards usually darker and the back of the haft greenish. There are many geographical forms of Iris ensata, some of which have been classified as distinct varieties. I. ensata is an easily grown and desirable species, although in gardens it usually does not commence to flower really well until well-established, usually about three years from planting.

New Orchid Species.—An enumeration of the Orchids collected by Mr. J. F. Rock on the Arnold Arboretum expedition to north-western China and north-eastern Tibet, is given by Mr. Charles Schweinfurth in a recent issue of the *Journal of the Arnold Arboretum* (Vol. X, 1929). Two new species are described by Mr. Schweinfurth, and these are Amesia longibracteata and Oreorchis Rockii. The former is a tall-growing plant, attaining a height of about 60 c.m. to the top of the inflorescence; in general appearance it recalls the widespreading and variable A. latifolia, but it has larger flowers, with more acuminate segments, than this species. Oreorchis Rockii is a small plant for the genus and it is found in alpine meadows at an altitude of 3,000 m. in central Kansu. Two new species of Orchids are also described by Dr. F. Kränzlin in the issue of Dr. Fedde's *Repertorium specierum novarum* for September 20 (Vol. XXVI). These are Catasetum stenochilum and Oncidium reductum. Catasetum stenochilum is related to C. Garnettianum and C. fimbriatum, while Oncidium reductum belongs to the Crucifera section of the genus and is a native of Brazil. The same publication also contains a technical description by Dr. J. J. Smith, of Bulbophyllum basisetum, a new species from the Phillipines.

Agricultural Machinery and Market Gardening.—The scientific application of agricultural machinery to market gardening in this country is foreshadowed in the announcement that at the World Tractor Trials, to be held near Oxford next year, special attention will be devoted to testing the efficiency of small mechanical equipment, such as tractor-cultivators, suitable for use by market gardeners. It is also announced that the Royal Agricultural Society of England, which is responsible for the Trials, has decided to modify the governing conditions so as to make the maximum entry fee £150 for all classes of tractors and machines. This limitation of the entry fees will add considerably to the financial liability of the Society, but the step is held to be justified by the encouragement offered to manufacturers of high-power equipment. On particular high-power cable sets and motor ploughs there will be a saving of £250 or more in entry fees, as compared with the amount chargeable under the original scale. The preliminary announcement of the Trials has attracted widespread attention both in England and abroad, and, for the first time in the development of agricultural machinery, it is anticipated that British firms will be in a position to meet the challenge of their American and Continental rivals.

Antwerp International Horticultural Exhibition.—Preparations are proceeding apace for the World's Fair to be held at Antwerp during the year 1930, in commemoration of the centenary of Belgian Independence, including the international horticultural exhibitions, which will be an important part of the show. A strong Committee has been appointed to arrange the horticultural classes, including MM. Van Orshoven (Directeur de l'Office Horticole), Emile Draps, Speckaert, Lt.-Gen. Cabra, F. Peeters, and Boddewijn, in the organisation of which the main responsibility falls on the Antwerp Royal Horticultural Society as the local society. A meeting of Group VI (Horticulture) took place at Brussels on November 6, under the presidency of M. Emile Draps, to make preliminary arrangements and appoint subject-groups to deal with the various sections, and the architect of the group, M. Van Marck, submitted plans of the proposed arrangements.

John Innes Institution Conference on Polyploidy.—A report in booklet form has recently been issued on the Conference on Polyploidy held at the John Innes Horticultural Institution, on January 19, 1929, to commemorate the centenary of the birth of the founder, John Innes. It contains the various papers which were read at this Conference, but no reference is made to the discussions which followed the reading of some of them.

Brighton's New Rose Garden.—Those who have known Brighton for any length of time are able fully to appreciate the enormous improvements that have been brought about in its parks and gardens during the last few years. The present Superintendent's project was a brilliant one when he opened out the valley gardens through the centre of the town by removing heavy railings, destroying literally thousands of Euonymus bushes, replacing them with spacious lawns and flower gardens. Then followed the laying-out of three new parks and the making of sunken gardens on the sea-front. The latter represent the finest work of its kind in the country. Brighton now possesses well over one thousand acres of parks and gardens, tastefully laid out and well maintained. But the latest effort has proved to be by far the finest improvement of all. Preston Park, which abuts on to the main London road, has been opened out and the south end laid out as a Rose garden, at a cost of over £13,000. The entrance to the town is thus vastly improved. Previously, visitors driving in by road would catch but a glimpse of the Park, which was bounded by severe and forbidding iron fencing and Euonymus hedges. One now gains the impression of entering the town by actually driving through a spacious and beautifully timbered park. The Rose garden is a masterpiece of design and execution, and has been praised by visitors from all parts of the world. In place of a none too attractive lodge, heavy iron gates, and dense shrubberies, a garden of unusual design has been laid out. The entrance is now emphasised by means of a broad sweep of roadway, the boundary being effected by means of imposing balustrading. The outline of the garden is determined by two roadways which diverge from points on either side of the entrance. The visitor enters from the south end onto a view which, therefore, broadens, and the design is so executed that the further boundary is undetermined, banks of flowers being visible so far as the eye can travel. The view through the centre of the garden passes over beds set out in lawns and sloping banks of faultless Cumberland turf. On the right background a pavilion of unusual design has been erected. The vista through the centre of the garden leads through trees to the distant Clock Tower, while on the left, one catches a glimpse of the bowling green, and again, in the far distance, the tennis courts. At the far end of the garden the paths turn inwards, leading through further Rose beds and terminating in a large circular pool. The design of the pool is commendable, and it provides a salient feature at the foot of the pavilion. The whole of this summer the garden has been a blaze of brilliant colouring provided by numerous bedding plants, for it was completed too late for the planting of Roses this year, but it is understood that over six thousand trees will be planted immediately. The whole of the work of design and execution has been carried out by Captain Maclaren, the able Superintendent of the Brighton Parks.

---

[*] "The Effects of Intensive Manuring on Two Varieties of Wheat," by F. C. Hawkes, M.A. *The Journal of the National Institute of Agricultural Botany*, Vol. II, No. 2, 1929, published by Messrs. W. Heffer and Sons, Ltd., Cambridge.

British Mycological Society.—A meeting of this Society will be held in University College, Gower Street, W.C.1, on Saturday, November 23, at 11 a.m. Professor R. R. Gates and Mr. D. V. Daran will deal with "Zygospore Formation in Mucors"; Miss J. Grove will discuss "Growth Reactions of Helotium scutula, Karst"; Dr. R. G. Tomkins will give an address on "The Relation of Mould Growth to Humidity"; Dr. H. Wormald will detail "Some recent observations on Brown Rot Diseases of Fruit Trees"; and Mr. E. C. Barton Wright will discuss "Sexual Reproduction in Penicillium." The names of the authors are arranged alphabetically. The papers will be given in the order most generally convenient. At this meeting the election of the President for 1930 will take place.

Utrecht Chrysanthemum Show.—The Annual Exhibition of Chrysanthemums and other autumn flowers was held this year from October 30 to November 3, in the market building at Utrecht. It had at first been intended to hold it at The Hague, but after the preliminary arrangements had been made, the organisers of the Rose Show, "Nos Jugunt Rosae," decided to have their exhibition in that town, and it was felt that a second exhibition so soon afterwards might not have been successful. The market building, although not in all ways well adapted for the purpose of an exhibition, proved quite suitable, and in the daytime the lighting was good; its over-large size and rather bare effect was greatly reduced by a generous and judicious use of ornamental plants. The show was opened in the afternoon of the first day by the Burgomaster of Utrecht, Dr. J. P. Fockema Andrae, who was received by the President of the Chrysanthemum Club. The number and quality of the exhibits was excellent, and the many prizes and awards were keenly contested. The Queen's Silver Medal was awarded to the firm of Messrs. Wed. P. Eveleens en Zonen, of Aalsmeer, for a really lovely group, and that of the Queen Mother to one almost equally fine sent by Messrs. W. Serton, of Vleuten. Messrs. Eveleens also won a Gold Medal, with a special cultural commendation from the jury, and Messrs. W. Serton obtained a similar honour, a Gold Medal being also awarded for a group of Codiaeums. Dracaenas and "Christmas Pepper," to Mr. C. Smitskamp, of Zeist.

Mr. J. S. Coates.—Mr. Coates commenced his horticultural career in 1905 at Wroxton Abbey Gardens, under Mr. D. Power, and after spending four years there he removed to Elvaston Castle Gardens, to serve under the famous fruit grower, the late Mr. J. H. Goodacre, V.M.H. There he remained for two-and-a-half years, during which time he was able to visit most of the important horticultural shows in the country. From Elvaston, Mr. Coates went to Moulton Paddocks Gardens, which were under the control of Mr. B. Goodacre. After serving under Mr. B. Goodacre for a period of two years, he obtained the post of foreman at Wynyard Park Gardens, under Mr. H. E. Gribble. Here he spent eighteen months, when the outbreak of the great war checked his gardening activities, and he joined the Rifle Brigade. He was drafted to France early in February, 1915, and after serving twelve months, mostly in the Ypres salient, was wounded at Hooge, and sent back to England. He was discharged from the service in August, 1916. In March, 1918, Mr. Coates was appointed to the charge of the gardens at Dalton Hall, Beverley, Yorkshire, which appointment he still holds. He is an active member of the North of England Horticultural Society, and has acted in the capacity of judge at the Society's shows at Harrogate. As an exhibitor of only two years' standing he has been fairly successful, winning the premier awards for Grapes and Pears at the last two shows of the Hull Chrysanthemum Society, and also the Silver Challenge Bowl for Japanese Chrysanthemums at the Beverley Society's show last year. The winning of the George Monro Memorial Cup for a collection of Grapes at the recent Royal Horticultural Society's Fruit Show was a notable achievement by Mr. J. S. Coates.

MR. J. S. COATES.

History and Development of the Chrysanthemum: Demonstration at Kew.—An exhibit is now to be seen at the Royal Botanic Gardens, Kew (House 14c), which attempts to illustrate the history and development of the Chrysanthemum. It is somewhat difficult, at the present day, to be certain of the exact origin of the garden races of a genus which has been the subject of cultivation for so long a time. In all probability the garden Chrysanthemums are descended from the two wild species now known as C. indicum, Linn., and C. morifolium, Ramatuelle. Flowering plants of these species are exhibited and also a specimen of C. ornatum, Hemsl., another eastern species, which, although it is one of the parents of one of the varieties in the exhibit, is not considered as having had much influence on the garden races now in cultivation. The earliest record of the Chrysanthemum being cultivated in Europe is in the year 1688, when it was being grown in Holland. It was also grown in the Garden of the Apothecaries Company at Chelsea in 1764. Examples of most of the present day races of Chrysanthemum are shown in the exhibit, which includes the Japanese (exhibition and decorative), Incurved, Pompon, Anemone-flowered, Singles and varieties with quilled and hairy petals, as well as some of early-flowering varieties suitable for outdoor cultivation.

The Royal Gardeners' Orphan Fund.—This deserving charity has received an anonymous donation of twenty-five pounds.

Cologne Exhibition.—From October 13 to 20 there was held at Cologne an exhibition of food-stuffs, of which the horticultural section was particularly interesting, comprising exhibits from several foreign countries, including France, Holland and Belgium. France exhibited Grapes from the open in the southern Departments; Holland had a huge exhibit of all kinds of produce, especially Grapes and Tomatos, and from Belgium came an excellent exhibit comprising many different kinds of products of the country. Belgian Grapes of all kinds were particularly to the fore, but perhaps the most important part of the exhibit consisted of the well-known Witloof Chicory, of which an enormous and ever-growing quantity is grown and exported.

Heavy Potato Cropping in Scotland.—The following are the results of the Potato-cropping competition promoted by Scottish Agricultural Industries, Ltd. (of which Messrs. Alex. Cross and Sons is the branch concerned):—First prize, Mr. John Hamilton, Mains, East Kilbride; yield, 23 tons 0 cwt. 0 qr. 11 lbs. per acre. Second prize, Messrs. Bryd Brothers, Lettrick Hills, Cambuslang; yield 22 tons 3 cwts. 2 qrs. per acre. Third prize, Messrs. R. and J. Logan, Kirkland, West Kilbride; yield 20 tons 10 cwts. 2 qrs. 24 lbs. per acre. The highest yield of other competitive counties, which include Dumbartonshire, Renfrewshire and Stirlingshire was 18 tons 10 cwts.

Scottish Horticultural Conditions.—The report of the Scottish Ministry of Agriculture for the quarter ended October 31, states that the exceptionally mild weather which prevailed well into that month enabled full crops to be gathered and blooms of tender plants were obtainable until an unusually late date. Reports from all districts regarding vegetables are satisfactory. As regards flowers, good results, particularly with Chrysanthemums, are reported from all districts. In the western area, however, some damage to the plants was done by leaf-miner. Abundant crops have been obtained in the Lothians, while in Midlothian, Dahlias, Marigolds, Tropaeolums and other plants, flourished and bloomed to the end of October. Prices obtained for flowers cultivated out-of-doors in the western area have been low. Satisfactory glasshouse crops were obtained in the northern and north-eastern area, but in the former prices were exceptionally low. Crops were below normal in the western area, where Tomatos suffered from a set back, but improved later. Red Spider, White Fly, Wilt Disease and Wireworms caused losses in the western area. Exceptionally good crops of small fruits were produced in all districts, Black Currants being particularly abundant in the western area. In the south-eastern area

Apples and Pears were harvested in good condition, but there were many windfalls as a result of gales in the early part of October. In the western area Winter Moth occurred on most trees, while Apple and Pear Scab was also rather severe.

Natural History of Basutoland.—An interesting part of the proceedings at a recent meeting of the Linnean Society was a lecture given by Dr. Hugh Scott, illustrated with lantern slides, of a natural history excursion into Basutoland. This excursion, made in February, 1929, during a holiday in South Africa, occupied only about eleven days. It was undertaken to see the general conditions in a little-visited part of South Africa, to collect so many insects as possible, and to compare this very mountainous country with other mountain regions where the lecturer's field work has lain. Basutoland is nearly 150 miles across in either direction. There are no railways except a mile or two linking up Maseru, the capital, on the north-west frontier, with the South African system. The few roads are all in the less rugged west borders, the rest of the country being penetrated only by bridle-paths. Until little over a century ago, Basutoland was inhabited almost solely by bushmen. The foundation of the present Bantu nation, the Basuto, by Moshesh in 1831, and their vigour and progressiveness, have profoundly affected the natural history. Deforestation and destruction of big game have been extensive. Almost the only native "timber" seen was scrub composed of a Rosaceous bush, Leucosidea sericea, about five to fifteen feet high. All arable land is devoted to cultivation of Mealies (Maize) and Kafir Corn (Sorghum), and the grassy slopes are stocked with horses and cattle. Entomological collecting resolves itself largely into "sweeping" grass and flowers, searching under stones and working the low, dense bush of kloofs. The country would doubtless repay prolonged investigation, which might reveal how far the insects of the mountains differ from those of the high veld surrounding Basutoland, and of the Cape Province mountains a long way south-west. Basutoland is a native reserve, but with the help of the local Commissioner at Maseru and other friends, an excursion was made thirty miles east from Maseru to Nyakoesuba, whence the Maluti Mountains were visited. Afterwards the extreme north-east corner was touched; a three-days' journey by horse was made from Witzieshoek, O.F.S., to the Drakensberg National Park in Natal, Basutoland being re-entered on the summit of Mont-aux-Sources, the highest mountain in South Africa, over 11,000 feet. On top is a flat moorland ending in a precipice more than 2,000 feet high, over which the Tugela River falls. Heavy rainstorms and high wind interfered with collecting on the summit, but the broken weather was compensated for by the profusion of flowers in blossom during the summer rains.

New Parks Superintendent for Durban.—From over thirty applications for the position of Parks Superintendent to the Durban Municipality, South Africa, Mr. P. Robertshaw, of Wynberg, Capetown, has been appointed by the Durban Town Council. Thirty-two years of age, Mr. Robertshaw holds high qualifications as a horticulturist. He commenced his career as a Horticultural Instructor in the English midlands, and was afterwards employed by the Parks Department of the Manchester Corporation. Later on, he took the student gardener's course at Kew, and subsequently assisted Sir Edwin Lutyens to organise a State Garden department in India. On Mr. Robertshaw's return to England he was offered the Curatorship of the Cambridge Herbarium: this position he declined, but accepted an appointment with a private employer in the Cape Province, which he took up a year ago. Mr. Robertshaw will undertake a complete reorganisation of the Durban Parks and Gardens Department, which in the past has suffered from a division of control.

A German View of Wisley Gardens.—In the November issue of the *Gartenschönheit* is an interesting article on the subject of the Royal Horticultural Society's Gardens at Wisley, with some excellent illustrations, by Karl Wagner, a sympathetic and appreciative visitor to this country. He states that, in commercial cultivation, Germany can in many respects give points to England, but in the sort of half-wild, half-cultivated garden which is this country's speciality, the English excel, and nowhere is this style of gardening—among others—to be better studied by foreign students than at Wisley. Herr Wagner took a keen interest in the trial grounds, and especially admired the condition of the Delphiniums, which was far better at the time of his visit than might have been expected after the frosts and cold winds experienced during the month of June in the present year.

Appointments for the Ensuing Week.—Monday, November 25: Birmingham and Midland Counties Gardeners' Associations' lecture. Tuesday, November 26: Royal West Renfrewshire Horticultural Society's meeting. Wednesday, November 27: Newcastle and District Horticultural Society's meeting. Saturday, November 30: Leeds Paxton Society's Show of Single Chrysanthemums.

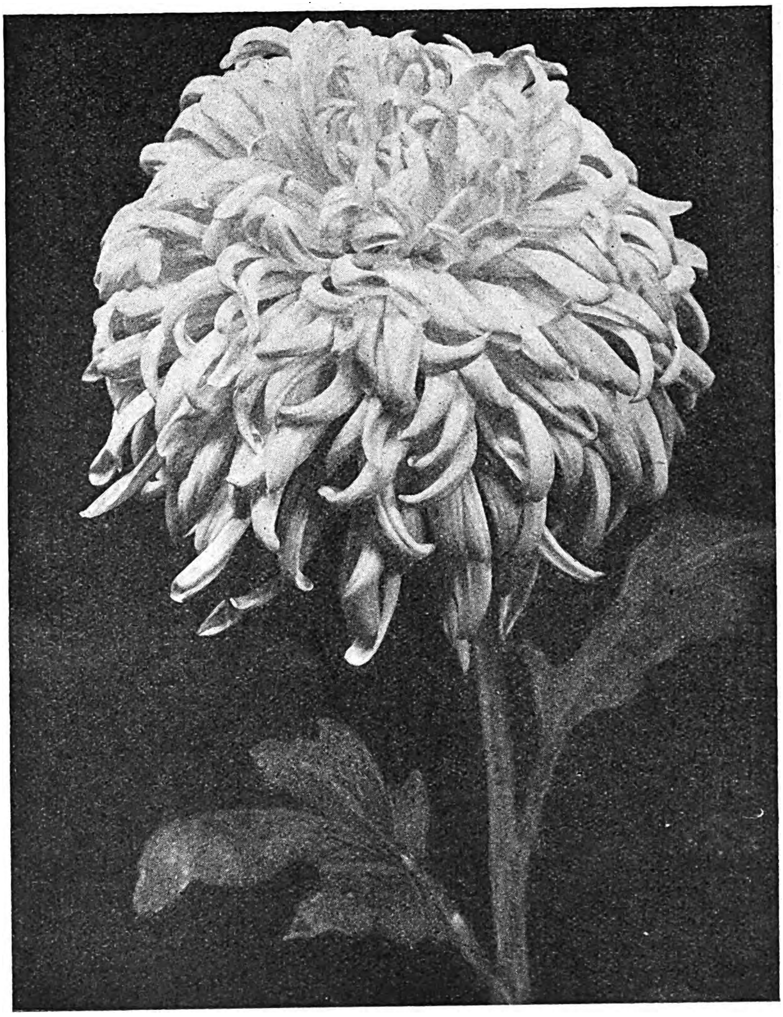

FIG. 181.—CHRYSANTHEMUM FLORENCE BIGLAND.

N.C.S. First Class Certificate, November 7. Flowers yellow. Shown by Mr. H. Shoesmith, junr.

(see p. 392.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*Mr. Salter's Versailles Nursery, Hammersmith.*—Those who are interested about new Chrysanthemums cannot do better than pay a visit to this nursery at the present time, while Mr. Salter's fine collection is in bloom. It contains all the novelties of importance both of last year and this, and will be found well worth inspection. The following are a few of the best of such as were in blossom on Monday last. Large-flowered kinds: August Mie, reddish salmon; L'Ingot d'Or, yellow; Albin, dark claret; Trilby, blush; Chevalier Dumage, golden yellow, large and showy; Cassy, red and orange; Triomphe du Nord, reddish chestnut; Bossuet, rose shaded with violet; Rolla, rosy purple, tipped and mottled with silvery markings; Conspicuum, shaded rose; Madame Lebois, delicate peach; Phare de Messine, dark chestnut; Hermine, blush tipped with rose, and one of the most beautiful of this year's flowers; Le Prophete, yellowish buff; Prince Jerome, yellow and brown; Duc de Rohan, light crimson; and Eclipse, straw-coloured. Pompones: Riquiqui, deep plum colour; Pluie d'Or, dwarf yellow; Hélene, purple; Doctor Duval, reddish chestnut; La Vogue, yellow with a brown centre; Madame Rousselon, delicate peach; Hector, dark orange buff; Comte Vigier, pale buff; Mdlle. Elkington, fine white; Rose Pompone, quilled, pale lilac Reine des Anemones, fine white; Consuolo, yellow; Berrol, sulphur, suffused with rose; John Salter, dark reddish orange; Brilliant, reddish scarlet; Bayardiere, buff, suffused with silvery markings; Rosita, blush lilac; Precoce, deep rose; and Mon. Bijou, pale fawn, shaded with lilac; Hybrids, *i.e.*, crosses between the Pompones and large-flowered kinds: Marabout, fringed white; Cedo Nulli, white with brown centre, a pretty kind; Marceau, lilac-tipped white; Bernard de Rennes, dark fawn; Golden Drop, yellow Anemone-flowered sort; La Radieuse, rose, with white centre; Madame Passy, rose, shaded with lilac; Aurore Boreale, yellowish-buff; Berthile, lilac, bordered white. These in general have larger flowers than the Pompones. *Gard. Chron., November* 25, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Cymbidiums.—Various members of this popular genus are now producing flower scapes, and such plants should be well supplied with water each time the compost approaches dryness, to assist the development of the flowers. As the flower spikes on some varieties are a considerable time—often three months—in developing, and the expanded flowers may remain in perfection for a long period, the strain on the plants is naturally very severe, therefore only well-rooted healthy specimens should be allowed to flower. It is best to remove the spikes from the weaker plants at an early stage. Lucious, soft-grown plants of Cymbidiums seldom produce flowers successfully, and the withholding of water at the roots to induce them to flower is of no use, or advisable. The roots often perish under this drastic treatment, consequently the plants deteriorate considerably. Although, naturally, less water is required during winter, they should never be subjected to long periods of drought. The majority of Cymbidiums require plenty of light and air during the growing season in order to induce them the flower successfully, only sufficient shade being required to prevent the foliage from injury by the strong sunshine. Under these conditions plenty of atmospheric moisture is required to maintain healthy growth, while the syringe should be used frequently to keep insects pests in check. At this season, when the syringe cannot be used so often, scale insects increase rapidly under the drier conditions, and these should be sought for and removed so soon as detected, using a small brush for the pseudo-bulbs and a sponge for the leaves, with a solution of an approved insecticide. Care should be taken to avoid injuring the young flower scapes and the growing points during this operation.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Pruning Wall Fruit Trees.—Every possible advantage should be taken of all open weather to push on with the pruning and training of fruit trees, from now until January, as by that time severe weather may be expected, causing delay to such operations until close on spring when other work such as spraying, etc., will demand our whole attention. Wall-trained trees on which the lateral growths were shortened to five or six leaves during the summer, should need but little pruning now, but whether summer pruning was practised or not, the growths should be shortened to three or four buds according to strength, and long, unsightly spurs, which can be replaced by fresh fruiting wood, removed altogether. There should be a judicious thinning of crowded fruit spurs, particularly on Pear trees, which bloom so profusely, and are sometimes followed by a disappointing crop of fruits. By carefully reducing the number of spurs, and the fruit buds in those retained, the energy of the tree may be concentrated on producing better blossoms and, generally, a better set of fruits may be obtained. For removing or thinning crowded fruit spurs, I have found that a joiner's key-hole saw, in addition to the ordinary pruning saw, is invaluable. This saw has a thin, narrow blade about ten inches in length, which screws into a Pear-shaped handle, and for this class of work will be found most useful, as the thin blade can be manipulated with safety where the ordinary pruning saw would cause injury. Where space permits, the terminal shoots on espalier-trained trees may be laid in to their full length, except in the case of young trees, the shoots of which will need shortening to encourage the development of spur or lateral growths. In pruning these terminal shoots, care should be taken to cut to a bud on the under side of the shoot. The tendency of this bud is to produce a strong growth a such an angle that it may be quite easily trained into the proper position. This is not the case when cut to a top or foreright bud. All large wounds should be pared smooth and covered immediately with some protective material to prevent the entrance of silver-leaf spores, or other fungus diseases. Various protective agents are from time to time recommended, such as grafting wax, which should be thinned down by heating and applied with a brush, either Stockholm or gas tar, and paint. Whatever agent is employed, it should have a good skin and be waterproof, and harden off without scorching the bark tissues, or cracking and shrinking at the edges of the wounds when drying.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Stocks.—These are useful subjects for winter and spring-flowering. Plants raised from seeds sown as advised, of the All the Year Round type, should never be allowed to get starved in small receptacles before being potted into their flowering pots, and so soon as these are well filled with roots, the plants should be fed with liquid manure. Stocks are best grown under the coolest possible conditions, therefore frames from which frost may be excluded and in which the plants may obtain a maximum amount of light, are the best structures in which to cultivate these subjects.

Cyclamens.—Those raised from seeds sown last August should, if all has gone well, be ready for pricking off into pans or boxes, in which they may be kept growing throughout the winter. For these seedlings the compost should be on the light side, using, if possible, plenty of old mortar-rubble and good, flaky leaf-mould, with some silver sand added. During the winter, they should be kept so near the roof-glass as possible in a temperature of 55° to 60°. A little care is necessary when applying water to the roots and especially if the temperature is allowed to fall below the above figures. The most forward of the flowering stock should now be allowed to develop their flowers, which should be useful during the Christmas season. The plants should be fed gently twice a week with diluted liquid manure, or soot water, alternated with an approved fertiliser. Mite often proves troublesome by attacking the flower buds, with the result that the flowers appear to be damping. These attacks should be checked at an early stage by the use of the sulphur vaporiser or XL insecticide.

Gladioli.—The early-flowering varieties of Gladioli are useful subjects to grow for early spring flowering, but to be successful with them no attempt at hard forcing should be made. Place about six corms in a six-inch pot, this size being the most useful receptacle to use for decoration in pots, but where the spikes are required in quantity for cut bloom it will be found much better to plant them fairly thickly in boxes, say, three inches apart each way, covering the pots or boxes with finely-sifted leaf-mould to the depth of two or three inches. They should be allowed to remain under these conditions until the roots are plentiful and the top growth is about two inches high, when light should be permitted to reach them gradually.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Pot Vines.—Pot Vines should now be thoroughly ripe and in satisfactory condition for starting early next month. Although pot vines have gone greatly out of fashion, growers who are obliged to produce early Grapes still grow or buy a few annually; they give an extension of time to permanent vines, and provided they are ripe and well-rooted, yield good crops of fruits. The vines having been shortened back to their proper length some weeks ago, there will be little danger of bleeding; nevertheless, a dressing with styptic is beneficial. When properly arranged, the soil carefully rammed, and lightly top-dressed with loam and bone-meal, a quantity of fermenting leaves with a little horse-manure added, may be introduced, care being taken that the top of the ridge does not exceed the level of the pots. Over this the canes may be suspended in an arched position where they may remain until the lowest buds are pushing freely. Fermenting material should be renovated when necessary; this will economise and soften fire-heat, and render direct syringing almost unnecessary. Careful watering with tepid water is very important. The temperature may range from 50° to 55° at night, and so high as 65° during the day, admitting a little air to keep the atmosphere sweet. Early permanent vines respond to similar treatment, but the roots, having the run of inside borders, should first be properly moistened by one or two applications of water at a temperature of 90° to 100°. The syringe, as a matter of course, should be used, especially on old stems near the pipes, dry corners, and other surfaces. The temperature may range as above, rising a few degrees higher by day with sunheat, but no advance should be made on the night figures given for some time.

Midseason Vines.—These should now be pruned, and the house cleansed and put in working order without delay, so that it may be kept cool and airy to ensure so long a rest as possible for the vines. If other plants must be wintered in these houses they should be of the hardiest kind, otherwise constant shutting up at night will affect the vines throughout the following season. When the vines are pruned and washed, the cuts may be dressed with styptic. All root work should have been finished, and top-dressing the borders will be the concluding operation. This should include the removal of inside mulching, pricking up the hard surface of the borders, and applying a thin layer of fresh compost. The roots, as a matter of course, should be fairly moist, but if autumn watering has been neglected it will be well to allow them to remain on the dry side for some time after pruning.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Anemone coronaria.—There are many fine strains of the Poppy Anemone, and the roots of these may be planted at any time from autumn until spring, when the ground is in good condition, but the best results are usually obtained by planting them during late October and November. Fortunately, this Anemone thrives in the majority of gardens, yet, for some unknown reason, it simply will not grow in others, even if special care is devoted to the preparation of the beds, and it simply dwindles away in a year or two. It loves a warm, deep loam, and the beds should be prepared by digging in some well-decayed manure and a little mortar rubble, making all firm by treading before planting. Choose a strain that has been well selected and contains a high percentage of bright colours; the results greatly depend on the care and attention in selecting the strains.

Anemone fulgens.—The scarlet Windflower thrives in a rich, well-manured soil and a lightly shaded position. The planting of this may also be extended over a few months, but as the resting period is from June onwards, it naturally follows the best results are obtained from roots planted during early autumn.

Lilies.—The present month is a good time for planting all species of Lilium, for all should, so far as possible, be transplanted while the bulbs are dormant, and as many begin to make fresh roots early in the season, no time should be lost in attending to transplanting where it is deemed necessary. The yearly importations of L. auratum and a few other kinds will not take place for a time yet, but where it is contemplated buying stocks of any, they ought to be procured at the earliest opportunity and planted in their flowering quarters so soon as received. In preparing sites for these, good drainage should be provided, so that no stagnant moisture remains around the bulbs during the winter. A good compost of rich loam, leaf-mould and sharp sand suits the majority of Lilies, and some are benefited by the addition of peat. Surface mulching with well-decayed manure and leaf-soil during the growing season is an important factor in the successful cultivation of Liliums.

Border Chrysanthemums.—Although most of these may survive the winter in the open in many districts, it is always advisable to lift a few roots of each variety to ensure sufficient stock for propagating from if required. These may be potted up or placed in boxes in a cold frame for the winter, where they will provide ample material to propagate from in early spring. If it is impossible to find room for them in a cold frame, the old stools should have some fine ash placed over and around them and some dry Bracken strewn over them during severe frosts; such protection will usually be sufficient to carry them through an average winter.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Vacant Ground.—When the ground becomes vacant it should be manured and dug and laid up so roughly as possible to weather, which is extremely beneficial to the soil. When trenching ground, collect any weeds, leaves and rubbish, and work them into the bottom of the trench, making sure they are well-buried. Newly trenched ground may be given a dressing of fresh shell lime, and when the ground is required in spring, this may be forked in lightly.

Parsnips.—These are best left in the ground and lifted when required, therefore, during frosty weather, it is advisable to cover the bed with Bracken or straw to prevent the soil being frozen hard and thus render the roots difficult to lift.

Carrots.—If frames are available, a sowing of Carrots may be made in a fairly deep bed of soil, to provide useful roots in early spring. After sowing the seeds, water the bed with a fine-rosed can, and keep the frames closed for two or three weeks until the seeds have germinated, when a little air may be admitted on all favourable occasions. The seeds should not be sown too thickly, and overcrowding of the young plants should be prevented.

Tomatos.—Plants intended for early fruiting should now be sturdy specimens in three-inch pots. These should be placed on a shelf where there is plenty of light and watered with care, as excess of moisture will soon cause damping-off. If cuttings are available of any good fruiting variety, and these are inserted in sandy soil, and when rooted potted off singly and grown on in a moderate temperature, they should make useful early plants and fruit earlier than plants grown from seeds.

Celery.—If not already attended to, the final earthing-up of Celery should be done at once. Make the ridge wide enough at the bottom to enable plenty of soil to be placed around the plants. Press the soil firmly around the collar of each plant, and during severe frosts, afford a covering of straw or other protective material.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Turnips.—Late-sown Black Stone or other Turnips are now ready for use, and should have some soil drawn up to them to protect them from frost. Swede Turnips should now be lifted and stored in a frost-proof shed, where straw or mats placed over them should keep them in good condition. If in large quantities, it may be necessary to store them in "pots" or clamps, when sufficient earth should be placed over them and well beaten with the back of a spade to exclude rain and frost, and a thatch of drawn straw placed over all and secured by ropes.

Parsley.—In most establishments Parsley is in demand all the year round, so that steps should be taken to preserve the plants. A frame placed over the bed ready to receive the lights on the first appearance of hard frost, is all that is necessary, but no coddling should be attempted, for the more air and light the plants receive the better and longer will they maintain the supply.

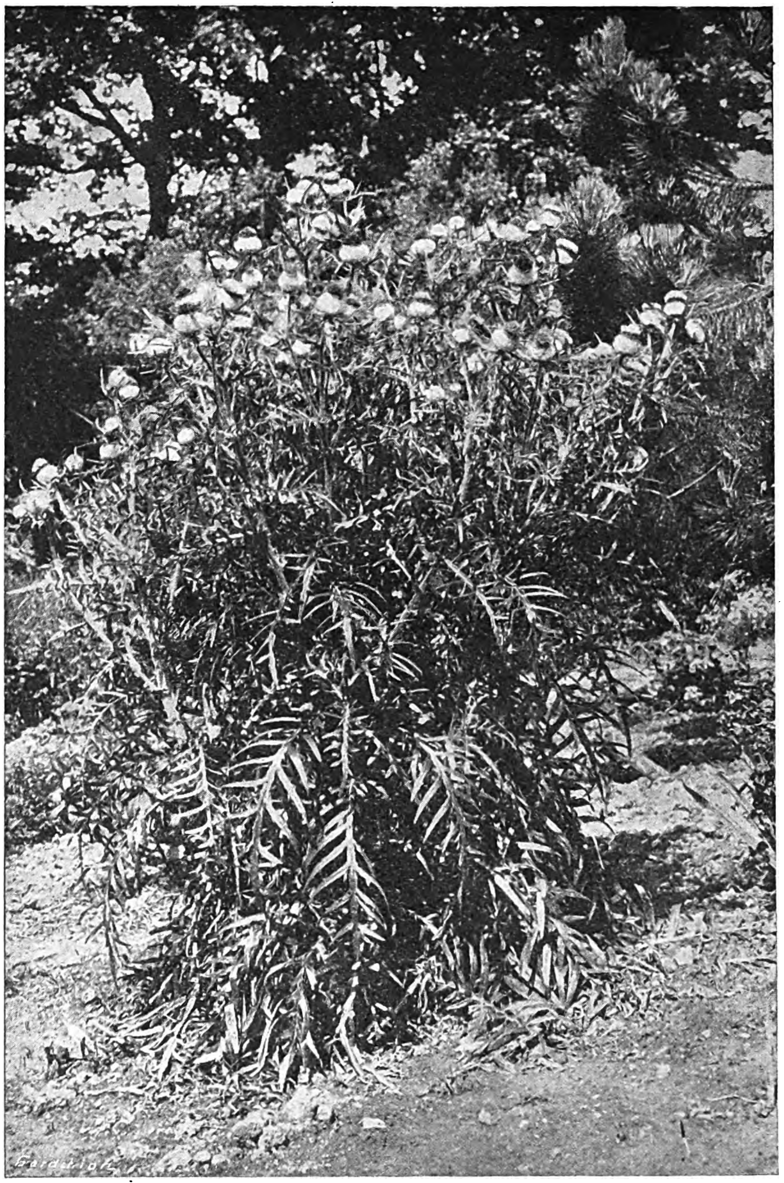

FIG. 182.—CNICUS ERIOPHORUS.

(see p. 402.)

Bulbs.—Hyacinths, Tulips and Narcissi which were potted or boxed up some time ago, should be examined at intervals, and removed from the plunging material when a good root-system has been established. Place them in cold frames from which hard frosts can be excluded, and move them into heat as required.

Winter Pruning of Wall Fruit Trees.—This work should be pushed forward so soon as the trees have cast their leaves. Being a cold job, it may be done more comfortably before the New Year than after. Where a supply of young growth has been laid in at summer pruning, a certain amount of re-arrangement of the branches will be necessary. A few of the oldest which have reached the limit of the space available should be removed with a pruning saw, the cut surface being pared off smoothly with a sharp knife, and the remaining branches spread out to cover the space. Breast-wood shortened in summer to four or five leaves should now be shortened to two or three buds. Any spurs which have become elongated, and project too far from the wall should be reduced or cut back completely. The leading shoots should be laid in full length, unless too vigorous, when they may be cut back to two-thirds their length; but where root-pruning is attended to regularly, such will not be necessary. Stone fruits resent hard pruning annually, and if sufficient young wood is left it materially reduces the amount made the following season. A serious attempt should be made to keep the branches straight, and this can only be done by attending to the young growths. In cutting back a leading shoot, cut to a bud facing the wall, and tie it close to the point of cutting. Examine all ties and replace those that show signs of causing damage. I prefer unwired walls, as I consider it almost impossible to produce a really good fan-shaped tree on a wired wall, and I have not, so far, seen one.

INDOOR PLANTS.

BAUHINIA YUNNANENSIS.

Linnaeus founded the genus Bauhinia in honour of the brothers John and Caspar Bauhin, authors, respectively, of *Historia Plantarum Universalis* and *Pinax Theatri Botanici*. The genus comprises some two hundred species, principally natives of the tropics.

The subject of this note is a most graceful, deciduous climber, and is an admirable subject for draping the roof of a cool greenhouse; a fine specimen grows in the corridor here. There is also a very fine specimen of it growing out-of-doors; it has flourished for many years in one of the bays that occur along the range of greenhouses, where it receives shelter and derives warmth from the wall of the Palm house. During the winter, suitable evergreen branches "tied in" give additional protection. The obliquely-elliptic, three- to four-nerved, glabrous leaflets, two in number, measure up to two inches long by one-and-a-quarter inch wide, borne on a rather stiff, inch-long petiole, and nestling between these twin leaflets is a flexile, awn-like growth some two lines long.

This climber has revelled in the past hot summer, producing its pendulous racemes in great profusion. Commencing to flower in July, it continued well into October. It belongs to the family Leguminosae and the sub-family Caesalpinioideae.

The pale pink blooms measure an inch across, the spathulate petals are pleasingly streaked with carmine, and the three upper ones have three or more streaks each, while the two lower have but a median one. The staminodes, seven in number, are inconspicuous, but the three perfect stamens bend downwards and are exserted some distance from the flower, displaying the carmine filaments; these, curling upwards, with the protruding and upcurled style, make a most attractive feature. The young growths may be terete, but are usually square-stemmed and grooved, while the main stems are flattened.

We owe the discovery of this plant to the indefatigable Abbé Delavay, who found it on the woody hills of Lokoshan, in the districts of Tapin-tze, in Yunnan. It was also found by Prof. Henry on mountains south-west of Mengtze, in the same province.

Bauhinia yunnanensis should present no difficulties out-of-doors in favoured districts, climbing by means of its flattened tendrils it would ramble over pergolas, trees, etc., and make an attractive feature. *J. Blades, University Botanic Garden, Cambridge.*

SCUTELLARIA MOCINIANA.

This very charming warm-house plant possesses many qualities sufficient to commend it to all lovers of indoor gardening, not the least being a propensity for producing its brilliant blooms in great profusion, and even small specimens create a fine effect when arranged on the side stages of the glasshouse. It succeeds admirably in a mixture of loam and leaf-soil with the addition of a little well-decayed manure and some sharp sand. Nice little specimens may be produced in five-inch pots, and, if desired, may be grown on into large plants. The young plants should be "stopped" once or twice to induce a bushy and compact habit of growth, and when old plants are grown on they should be pruned well in early spring before being repotted. Cuttings of half-ripened shoots root readily at almost any season, and soon form effective specimens. Almost every shoot terminates in a truss of brilliantly-coloured, Labiate flowers, the corolla being bright scarlet and the interior of the lip yellow; the tube is clothed with minute hairs, and the limb is erect. The petiolate leaves are ovate, hispid above, glabrous beneath.

S. Mociniana thrives in an intermediate temperature and is classed as a summer-flowering plant, but in reality it is in flower for the greater part of its growing season. Introduced from Mexico in 1868, this brilliant plant well merits extended culture, especially as the flowers last well when cut. *Ralph E. Arnold.*

COLUMNEA GLORIOSA.

A native of Costa Rica, and closely allied to Aeschynanthus, this late-flowering indoor plant is named after Columna, an Italian writer on plants in the sixteenth century.

It makes a good hanging basket subject, its fine scarlet and yellow flowers showing prominently above the reddish-purple foliage.

C. gloriosa imparts a charm to any stove during the winter months, and even when the flowers are waning somewhat, its long stems clothed with coloured foliage and hanging from the basket, make it quite attractive.

AESCHYNANTHUS BRACTEATA.

A native of India, Aeschynanthus bracteata should have a place in every stove. Being epiphytic, good drainage is absolutely necessary to its well-being, and it should be grown in suspended baskets after the manner employed for some Orchids.

Chopped Sphagnum-moss, fibrous loam and fibrous peat should form a suitable compost for this Aeschynanthus, the flowers of which are scarlet and yellow, and are most welcome at this season of the year. Aeschynanthus bracteata delights in a humid atmosphere.

BIGNONIA BUCCINATORIA.

A native of Mexico, this is one of the most beautiful climbers in blossom now, under glass in the Botanic Garden, Edinburgh, for its long, tubular flowers make it most attractive. It requires plenty of room, and should be trained to the roof of a tall greenhouse. Its leaves are divided into three leaflets, the middle one often forming a tendril or hook as a means of climbing. The flowers are red in colour, with an orange throat, tubular and usually about four inches in length.

Like most tall-growing climbers, B. buccinatoria succeeds best when planted out in prepared borders and the main stem trained up to the roof, where the shoots will be exposed to plenty of sunshine. The conspicuous colour of the flowers make it an acquisition among indoor plants during the autumn. Bignonia Cherere is a synonym, and under this name it is known to many. *D. W., Edinburgh.*

HARDY FLOWER BORDER.

CNICUS ERIOPHORUS.

Cnicus eriophorus, Roth., is a comparatively rare British plant, and forms a most handsome object where there is space available to grow it. The specimen illustrated (Fig. 182), grown at Brockhurst, measured seven feet six inches tall, and the flower heads were about as large as golf balls.

The plant is usually found on limestone soils, but the specimen figured was grown in our ordinary garden soil, with no limestone at all, and is a far finer plant than I have ever found wild. *Frederick J. Hanbury, Brockhurst, East Grinstead.*

PAEONIA FORRESTII.

This species is, at least superficially, very like Paeonia lutea, differing chiefly in the greyish-green, or almost bluish-grey, colour of its leaves, in having rather more ample growth, and in the somewhat larger flowers, the brownish-red basal colouring of the deep yellow segments being most pronounced.

P. Forrestii is an easily-grown species and a good plant for the border or semi-wild garden; as with many of the Paeonies, it enjoys an abundant supply of good leaf-soil and, when once established, immunity from disturbance.

It is, in my opinion, a better garden plant than P. lutea, primarily by reason of its attractively-coloured foliage and rather larger flowers, but there is a fascination attaching to most of the now numerous Paeony species, and they may well play, in time, a quite large part in the embellishment of the less formal parts of the garden. *R. E. A.*

TREES AND SHRUBS.

EUONYMUS RADICANS VAR. KEWENSIS.

Among the varieties of Euonymus radicans there are several very useful shrubs for the rock garden. The variety foliis variegatis is a well-established favourite, and Silver Queen is a variety which may frequently be seen on the show stand. Incidentally, the writer would suggest that Ivory Queen would be a name better descriptive of this variety, since the plants which he has grown were ivory, rather than white, in their variegations; it also lacks the graceful habit of those varieties which are definitely climbing or creeping in their growth, such as foliis variegatis.

Euonymus radicans var. kewensis does not appear to be so well known as it deserves, although it has the advantage of passing under the varietal names of minimus and microphyllus, in addition to that quoted above. Both these alternative names adequately describe the plant, which is a completely dwarf edition of E. radicans, possessing certain other distinctive and useful characters. For instance, the leaf-veins are light green in colour and change to crimson in the autumn, so that the plant lights up its own foliage solely by means of the tinted veins. Apart from the veins, the leaves are dark green and of some substance, generally less than half-an-inch in length and half as wide, ovate, and the margin is practically entire, although more or less rolled in such a way as to hide the few minute teeth which may or may not be present.

In the garden, E. r. var. kewensis forms a lovely little tangled mat only two or three inches high, which will trail along the ground or over a rock until it reaches anything that will afford support. Thereafter it will climb by means of its twining, wiry stems. If support is lacking, the plant gradually increases in diameter by means of the trailing shoots which are thrown out in all directions. Upward growth is very slow, but the centre rises until in extreme old age, it is a twisted mat of interlacing stems.

E. r. var. kewensis flourishes in sun or shade, and is not particular as to soil, although it probably prefers the compost to be fairly light. It should be planted in front of or behind a large rock, which it will ultimately clothe in a hummock of dull, dark green (changing to a richer tone as the season advances), provided that it can be induced to grow in the right direction.

This indispensable shrub was introduced by the late Professor Sargent, who brought it from Japan and introduced it to this country through the medium of Kew. *L. C.*

VIBURNUM TINUS.

Although such an old favourite in the gardens of all classes, Viburnum Tinus (Laurustinus) is still one of the most useful of evergreen shrubs by reason of its hardiness, its winter-flowering—it is in bud and flower from October to April, inclusive—and its adaptability to shaded and dry, starved places. It makes an especially good undergrowth for tall trees, although absence of sun lessens its freedom of flowering, or even stops it altogether. It is surprisingly hardy for a native of the Mediterranean and south-east Europe, and came through 20° of frost last winter uninjured, although some of the trusses of flower buds were killed where most exposed to the east wind. It succeeds, more or less well, in any reasonable soil, but does best on warm soils, especially near the sea. Its one shortcoming is that the flowers and buds soon drop when cut.

It is one of the easiest shrubs to propagate, either in the autumn, or by well-ripened shoots in June or early July. Growths touching the ground often root naturally or are easily induced to do so by placing a heavy stone on them. Cuttings I put in a cold frame in June, 1921, are now plants six feet high and as much in diameter.

There are several varieties of this shrub. V. T. var. lucidum has larger leaves, flowers and trusses, but is less hardy and not so compact; var. hirtum is very vigorous and has downy leaves; variegatum has golden-yellow variegated leaves; and pyramidale is a good subject for a garden hedge, not clipped, of course, but kept in shape by judicious pruning. *A. Petts.*

ABUTILON MEGAPOTAMICUM.

ABUTILON megapotamicum (syn. A. vexillarium), a shrub belonging to the Natural Order Malvaceae, was introduced from Rio Grande in 1864. The graceful habit and beautiful colour of the flowers present a very pleasing spectacle, and make this shrub worthy of consideration as an addition to the garden.

The flowers, with dark red sepals, pale yellow petals, and dark brown stamens which protrude from the centre beyond the petals, form a fine colour contrast. Being pendulous and bell-shaped, they are of striking appearance. The leaves are small and pointed, and are borne on stems which attain a height of three to six feet if grown against a south wall, an aspect in which this shrub may be considered hardy. In this position it will flower from late summer until winter.

This Abutilon may be propagated easily from hard-wooded cuttings, taken either in September or early spring, inserted in a compost of equal parts of loam, peat and leaf-mould, with the addition of some sharp sand, and placed in either a cool greenhouse or frame until May, when they should be planted out. *R. E. Moore, Botanic Garden, Cambridge.*

ALPINE GARDEN.

CAMPANULA GARGANICA VAR. MAJOR.

A VERY beautiful effect is produced here by a couple of plants of this fine variety of the variable Campanula garganica on the face of a dry, double rock wall.

Planted at the base of an abutment, this Bellflower has spread freely and has found its way along the face of the wall, lying as close to it as if it was a self-clinging plant. It is much admired, as its fresh green leaves are accompanied by hosts of large, flat flowers of blue, with a white centre. The other plant is almost equally fine, on another low wall, where it is planted so that it had only a foot or so to clamber along the face until it reached the level top of the low wall. This it has done and presents a charming picture as well.

This is one of the finest forms of C. garganica, although I have a special liking for the lighter coloured C. g. var. hirsuta.

VERBENA CHAMAEDRYOIDES.

THE reference to this plant in the "Notes from Edinburgh" (p. 345) as being tender, induces me to write a short note regarding it, especially as I had flowers sent me a month or two ago from a rock garden in Scotland, where it had been planted under the impression that it is hardy. The late Reginald Farrer made some pertinent remarks concerning it in *The English Rock Garden*, and readers who have this work may look it up if they think of adding Verbena chamaedryoides to their collections.

This bright scarlet Verbena, which came from Buenos Aires in 1837, attracts the notice of all by the brilliance of its flowers, and a good plant trailing over the rockwork and well dowered with its heads of flowers, is not one which will be passed by without admiration. Yet it is too tender for many gardens, save those in the most favoured localities in the south and south-west and, even there, is not to be relied upon, so that the precaution of rooting some cuttings in early autumn, to be kept under glass, is a wise one unless the owner of the garden is prepared to purchase plants annually.

This Verbena is probably the hardiest of all the plants of the genus, but I have never tried the species called V. venosa, which has heliotrope-coloured flowers, and which also comes from Buenos Aires, and I believe it is no hardier than V. chamaedryoides, if as hardy.

But, as Farrer stated, "No Verbena worth the growing is really safe and hardy and capable of permanent establishment in any average English garden." With this I cordially agree. *S. A.*

SAXIFRAGA FORTUNEI.

THE note by Mr. Will Ingwersen on page 342 regarding Saxifraga Fortunei is a timely one, seeing that at the late season at which it blooms it is of much value in the rock garden. These late-flowering plants are always keenly appreciated by the lover of the rock garden, and such information regarding this Saxifrage as is given by Mr. Ingwersen is welcome.

S. Fortunei is so nearly hardy that it should be grown wherever possible, and one is interested in learning that Mr. Ingwersen grows his plant in a cool corner of rich soil. In ths district, where we have an average rainfall of about fifty inches per annum, I should hesitate to plant S. Fortunei in rich soil, and have found it advisable to keep it in the moraine and in a sunny place. I had one plant in a moraine with a small proportion of old mortar-rubble in the compost and facing full south, for half-a-dozen years without any protection in winter. It eventually succumbed to a severe frost.

This Saxifrage deserves all the praise given it by Mr. Ingwersen, and I hope readers who have their gardens in mild localities will bear it in mind when adding to their plants. *Dumfriesshire.*

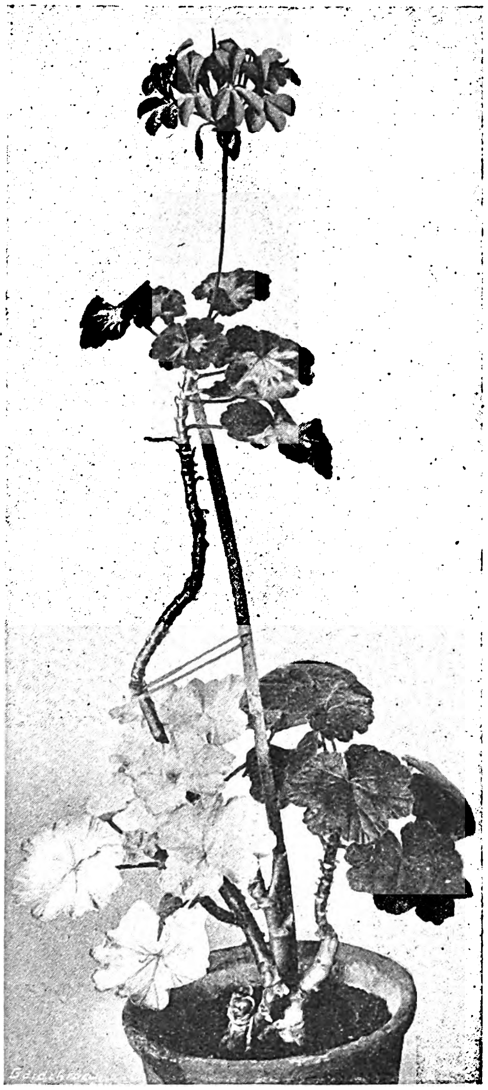

FIG. 183.—PELARGONIUM HAPPY THOUGHT.
Showing white, green and variegated leaves.
(see p. 405.)

NOTES FROM EDINBURGH.

AMONG the many plants now ripening their growths, several are conspicuous owing to the beautiful colouring of their foliage.

In the collection of Barberries, B. aggregata var. Prattii, with coral-red berries and coloured foliage, is a desirable plant; it seems to berry well in all seasons and almost in any position. The long, arching stems of B. dictyophylla, covered with white meal, contrast with its brightly coloured foliage, while among the many other Berberis species now attractively tinted with red are B. Coryi, B. aemulans, B. capillaris, B. virescens and B. Wilsonae. A different note is struck by the soft yellow shades of B. sinensis and B. brachybotrys.

Near to the collection of Barberries are the many species and varieties of Oaks. Here, owing to their stature, the various shades are more pronounced. Yellows and light browns predominate, and although these are beautiful, the most outstanding plants are the Scarlet and Red Oaks, Quercus coccinea and Quercus rubra, respectively. It is a great pity that these two species are not planted more frequently, as they are noble trees throughout the season, and during this period of the year, give a wealth of colour.

Another subject well worth growing for its beautiful autumn colouring is Zelkova crenata; for the last three or four weeks the pink and red shades of its foliage have made it very effective against the dark background of a group of Pines. Beside the hedge of Rhododendron praecox, its leaves now turning yellow, the many species of Enkianthus have given a variety of tints; the most prominent being E. cernuus, dull red, and E. tectus, soft yellow.

From the top of the hill overlooking the valley which runs through part of the garden, a great array of colour is seen. From this view-point many subjects stand out by reason of their strong colours. Here, again, the Scarlet Oak brightens the scene in contrast with the many shades of yellow and orange. Down in the valley can be seen a tree of the purple-leaved Sycamore, its leaves now reddish-purple. The many species of Pyrus and Prunus also contribute to the general bright colour scheme.

Among the many species of Pyrus, one of the brightest is P. Aucuparia var. discolor. This plant, viewed against a neighbouring Yew, has been a glorious combination of colour. The foliage was tinted yellow on the lower branches, gradually changing to a pinker shade until, at the top of the tree, the leaves were a bright pink. Among the recently introduced species, P. Sargentiana, with its large leaves now red and gold; P. Wilsoniana, with bright red foliage; and P. Vilmorinii, dull red, are all good subjects for autumnal effect.

In the other sections of the genus, Pyrus Toringo, with scarlet fruits and golden foliage showing well against the background formed by a large Yew, is very striking, while near the pond, the Wild Service Tree, P. Torminalis, was a blaze of reddish-bronze.

The various species and varieties of Prunus before they finish their growths take on delightful shades of yellow and bronze, the most charming at present being P. serrulata, a mass of pinkish-bronze.

Reflected in the pond can be seen the many tints of the surrounding plants. At the west end, the graceful Salix daphnoides, its leaves now golden-yellow, is viewed above a flame-coloured plant of Euonymus alatus. At the other end, the browns of the Taxodium distichum and Quercus imbricata, contrast with the yellow of the Iris species planted at the edge. A plant that never fails to attract attention at this season is Stranvaesia Davidiana, a mixture of bright red and green.

A genus of plants which always proves interesting at this season is Cotoneaster, with bright berries and richly coloured foliage. Owing to the great number of closely allied species and varieties, it is extremely difficult to make comparisons, but mention may be made of a few which now brighten the rock garden. The well-known C. microphylla, covering a mound, is very striking, its scarlet berries being seen to effect among the dark green leaves. C. horizontalis is attracting attention by taking on a mixture of all shades—best described as a coat of many colours. The variety perpusilla is quite distinct, with its leaves now reddish-purple. Another, with a similar type of growth, C. adpressa, is now dull red. At the entrance to the rock garden one of the larger species, C. divaricata, although not fruiting so well as some of its relatives, is a blaze of scarlet.

The most striking subject on the rock garden is Berberis Thunbergii, now a bright mass of orange, orange-scarlet and scarlet. Planted on a prominent part of a mound, it can be seen from some distance.

Among the several interesting subjects under glass, mention may be made of Dichorisandra thyrsiflora, a native of Brazil, which has handsome blue flowers borne on stems five to seven feet high, clothed with dark green leaves about nine inches long.

Momordica cochinchinensis, from tropical Asia, an ornamental climbing Gourd, is in fruit and is very striking, its large, red, spiny, oval-shaped fruits suspended from the roof making this subject an attractive feature in the tropical stove.

Rhodochiton volubile, a native of Mexico, is a handsome greenhouse climber, its pale red calyces making it effective at the present time.

Another plant worthy of mention is Fuchsia bacillaris, from Chile, which is planted out in a small alpine house. Its growths are now laden with reddish-pink flowers, and it is highly attractive. *David Wilkie, Royal Botanic Garden, Edinburgh.*

THE GENUS PRIMULA.

(Continued from p. 388.)

SPECUICOLA (Rydb.). Bluffs P.
(Farinosae).

THIS dwarf perennial is a sub-species of P. farinosa. The short rootstock produces a tuft of thin leaves two to five inches long, with elliptic, blunt blades gradually tapering to a winged stalk; margins sinuately toothed; both surfaces slightly mealy when young, smooth when mature. Flower stem barely one inch tall, bearing an umbel of ten to twenty dark violet blossoms with yellowish tubes, on stalks half- to three-quarters-of-an-inch long. Corolla flat, or slightly concave, about half-an-inch across, with wedge-shaped, broadly-notched lobes; tube cylindrical, about half-an-inch long. Flowers from February to August.

Grows in loose soil under overhanging limestone cliffs, along the San Juan River, near Bluffs, in Utah, U.S.A.

Culture: Plant it in good, friable, calcareous loam in a fairly damp, shady spot.

SPHAEROCEPHALA (Balf. f.). Spherical-headed P.
(Capitatae).

A handsome plant closely allied to, if not a sub-species of, P. capitata, with a tuft of non-downy foliage which is contemporary with the flowers; the leaves are three to five inches in length and have narrowly oblong or broadly lance-shaped, thin, blunt or sub-rotund blades, tapering to short, winged stalks; margins irregularly toothed as though gnawed by insects. Flower stem about twelve inches tall, stout, coated with white meal towards the tip, bearing a spherical head of many dark purple, delicately scented blossoms. Corolla concave, about half-an-inch across, divided into five broadly wedge-shaped or nearly square, deeply notched lobes, at times with a tooth in the sinus; tube cylindrical, dilated upwards, about three-eighths-of-an-inch long, reddish externally. Flowers in September. In cultivation in 1920.

Grows in marshes in openings in Pine woods, and in stony alpine meadows, in north-western Yunnan, western China, at 10,000 to 14,000 feet above sea-level.

Culture: As for P. capitata.

SPICATA (Franch.). Spicate P.
(Soldanelloidae).

An extremely delicate annual or biennial species with relatively large blossoms on such slender stems that they sway with the least breath of wind. The rosettes of membranous leaves have oval or oblong-oval, blunt blades tapering somewhat abruptly into narrowly-winged stalks longer or shorter than the blade, in all one-and-a-half inch to three inches long; margins sharply toothed; both surfaces covered with short, glandular, meal-producing hairs. Flower stem very slender, four to eight inches tall, bearing an elongated umbel or spike of stalkless, horizontal or somewhat pendulous, bright blue, faintly fragrant blossoms. Corolla three-quarters- to one-and-a-quarter inch across, slightly concave, with oval, notched, irregularly toothed lobes; tube short, scarcely so long as the calyx. Flowers in September and October. Illust. in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913. Introduced in 1908.

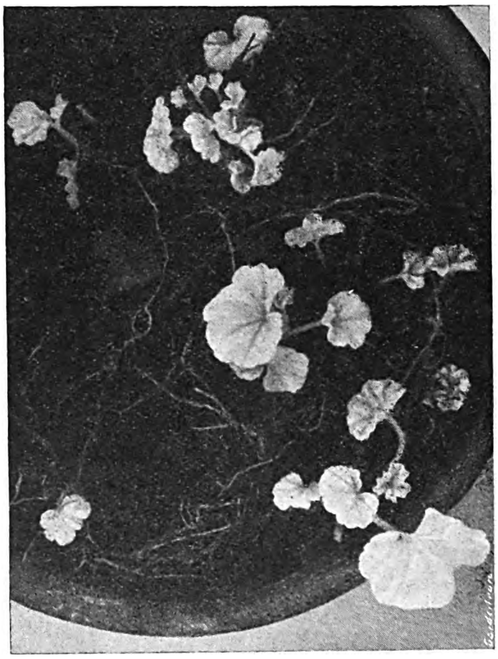

FIG. 184.—PELARGONIUM HAPPY THOUGHT.
Showing albino cuttings from inverted roots.
(see p. 405.)

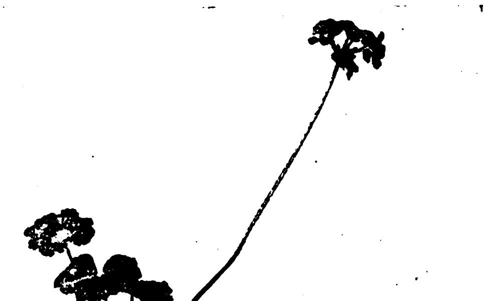

FIG. 185.—PELARGONIUM MRS. POLLOCK.
Showing green-leaved plant (left) raised from a root-cutting.
(see p. 405.)

Grows on dry rocky slopes and on the ledges of cliffs in valleys, in open, sunny spots, on the eastern flanks of the Tali range, in western Yunnan, western China, at about 11,000 feet above sea-level.

Culture: Grow it in good fibrous loam with plenty of grit, in an open, sunny, well-drained spot.

STENOCALYX (Maxim.). Narrow-calyxed P.
(Farinosae).

A pretty, deciduous, perennial species with a rosette of rather flaccid leaves quite devoid of meal, with oval or spathulate, blunt blades, tapering to a short, winged stalk dilated and sheathing at the base, in all two to four inches long; margins usually quite entire, or obscurely toothed. Flower stem four to nine inches tall, bearing an umbel of about six lilac or lavender-blue, rarely white, fragrant blossoms. Corolla about one inch across, with short, rounded, bilobed, notched segments; tube cylindrical, about as long as the calyx.

Grows in dry, loose soil, on warm, sunny banks on alpine moorlands on the mountains of western Kansu, in north-western China, at 8,000 to 11,000 feet above sea-level. In cultivation in 1920. *Gard. Chron.*, 1915, Vol. LVIII, p. 332, Fig. 117.

Var. dealbata (Farrer) has stiffer leaves than the type, with more egg-shaped- wedge-shaped blades and regularly toothed margins; both leaf surfaces more or less covered with white meal. This form grows under the same conditions as the type, but is found at an elevation of 13,000 feet above sea-level.

Culture: Good, friable loam and grit in an open, sunny, well-drained spot, should suit them.

STIRTONIANA (Watt). Stirt's P.
(Minutissimae).

A delightful little Himalayan perennial species of very dwarf, tufted habit, with egg-shaped, spathulate leaves, rounded at the tip, tapering at the base into a more or less distinct, narrow stalk, in all from half- to three-quarters-of-an-inch long; margins regularly and sharply toothed; both surfaces clothed with fine glandular hairs, non-mealy. Flower stem obsolete; flower solitary, purple, on a short, slender stalk sunk among the leaves. Corolla concave, half- to five-eighths-of-an-inch across, with broadly heart-shaped, very deeply notched, entire or bluntly toothed lobes; tube cylindrical below, dilated upwards, about twice as long as the calyx. Not in cultivation.

Grows in patches in stony soil on the slopes of the Kanglanamo Pass, in the Sikkim Himalayas, at 14,000 to 16,000 feet above sea-level.

Culture: Peat and gritty loam in a well-drained, open situation, with underground moisture when the plant is in growth and protection from damp in winter, are the conditions suggested.

STOLONIFERA (Balf. f.). Stoloniferous, Toothed P.
(Denticulata).

This deciduous perennial is probably a sub-species of P. denticulata, it produces several compact rosettes of more or less smooth, non-downy foliage from large, naked stolons about two inches long. The leaves, which are well developed at flowering time, are about three inches long and have broadly lance-shaped or narrowly egg-shaped-oblong, blunt, membranous, non-mealy blades tapering into short, winged stalks; margins furnished with large or small, blunt or saw-like teeth. Flower stems four to twelve inches tall, thickening when in fruit, smooth below, more or less mealy upwards, bearing a few-flowered umbel of pale rose, rose-lilac, or violet, fragrant blossoms with an orange eye. Corolla flat, about five-eighths-of-an-inch across, with egg-shaped, very deeply-cleft segments; tube cylindrical, slightly dilated upwards, equalling the calyx in length, more or less mealy externally. Flowers from March to May.

Grows in marshes and on the banks of streams in the valleys of the Tali and Lichiang ranges, in Yunnan, western China, at about 8,000 feet above sea-level.

Culture: As for P. denticulata, with protection from frost in winter.

STRAGULATA (Balf. f.). Kiuchiang P. (Bella).

A very beautiful little perennial plant of dense, compact habit, with close rosettes of numerous pale green, wedge-shaped leaves tapering to a short stalk, in all hardly half-an-inch long; margins above the middle very deeply incised, below the middle entire; both surfaces the same tint and covered with minute, meal-producing, glandular hairs. Flower stem slender, about five-eighths-of-an-inch long, covered with meal-producing, glandular hairs, and bearing a solitary, rich purple-rose blossom with a white eye, about five-eighths-of-an-inch long, and the same measurement in width. Corolla with spreading, deeply divided lobes; tube twice as long as the calyx, with a dense tuft of snow-white hairs in the throat. Flowers from June to August.

Grows in stony alpine pastures on the mountains of the Salween-Kiuchiang Divide, in south-eastern Tibet, and in moist, peaty moorlands on the Beimashan, in north-western Yunnan, at 14,000 to 15,000 feet above sea-level.

Culture: As for P. bella, of which it is considered a sub-species. *A. W. Darnell.*

(To be continued).

PLANT VARIATIONS.

(Continued from p. 385.)

SPORTS, CHIMAERAS, VARIEGATION AND MUTATIONS.

PELARGONIUM ZONALE VARIETIES.

MANY varieties of these plants have silver or white-margined leaves, *i.e.*, white skin over a green core. These frequently produce green-leaved sports from the stems and also from the roots. Propagated by means of root-cuttings, they give rise to green-leaved plants, *e.g.*, May Queen, Chelsea Gem, Flower of Spring, Caroline Schmidt, etc.

Such varieties as Freak of Nature and Happy Thought (Fig. 183) which have white or yellowish leaf-centres and green margins, also produce green-leaved and albino sports, and when grown from root-cuttings, white shoots only are produced (Fig. 184). These, owing to the absence of chlorophyll, soon die.

It may be of interest to state that Freak of Nature, in its normal variegated state, flowers, but fails to set seeds. The green-leaved sport is quite fertile, and produces green-leaved plants from seed. The albino shoots also produce flowers, and seeds are formed. The resulting seedlings, however, are pure white and rapidly die. Some albino shoots have very small, green ticks or patches on the stipules, and seeds from such shoots will give an occasional green seedling.

In the case of Happy Thought, the seedlings come green. No breeding up to the present has given us any plant like either of the parents.

Varieties having whitish stems, petioles, peduncles, and pedicels, and also having the centres of the leaves of a pale colour, due to a green skin over the white core of the plant, always give rise to white shoots when propagated by root-cuttings, *e.g.*, West Brighton Gem, and the green-over-white forms of many varieties such as Freak of Nature, Paul Crampel and Flower of Spring.

The variety Mrs. J. C. Mappin has variegated leaves similar to Flower of Spring. The flowers are whitish. It was raised by W. H. Townshend, gardener at Clapham Park, and was sent out by H. Cannell (*Gard. Chron.*, 1877, Vol. ii, pp. 18, 119). In *The Garden*, 1881, Vol. xix, p. 121, it is stated that this variety sometimes "sports." This variety occasionally produces red flowers and whitish flowers on the same plant. It also produces green-leaved shoots having red flowers, and also shoots in which the leaves are green-over-white. In this case the flowers are of the whitish colour of the typical plant.

Root cuttings raised from a typical whitish-flowered and variegated-leaved plant have all had green leaves and red flowers.

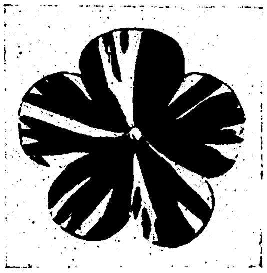

FIG. 186.—PELARGONIUM NEW LIFE.

Zonal tricolor Pelargoniums, such as Mrs. Pollock, when propagated by root-cuttings give rise to green-leaved plants (Fig. 185).

Zonal bicolor Pelargoniums, such as Golden Harry Hieover, come true from root-cuttings.

Pelargonium Kleiner Liebling, a very dwarf, small flowered plant obtained from Germany, gives a much larger plant with larger flowers when grown from root cuttings.

Pelargonium New Life is a variety reputed to have originated in the Isle of Wight about 1876, as a sport from Vesuvius. This has single, scarlet flowers, with irregular, white stripes on the petals (Fig. 186). It has almost disappeared from gardens. The plants grown at Merton, although in perfect health, and producing an abundance of flower buds, yet fail to develop open flowers. Eight plants were raised in 1927 from root cuttings, all of which resembled the parent plant. The plant is figured in *The Floral Magazine*, 1877, t. 288, and *Gard. Chron.*, 1877, ii, p. 203 and 1878, i, p. 204-5. Pelargonium Double New Life, a sport from Vesuvius, introduced in 1892, has small, double flowers. The ordinary corolla is apparently suppressed and the flowers are made up of small, red and white petal-like growths, probably modified petals and stamens. It will sometimes produce normal scarlet flowers among the abnormal ones. When grown from root-cuttings and from seeds, this plant produces normal, single, scarlet flowers, indistinguishable from Vesuvius. The typical double form produces seeds when pollenated from the single-flowered form.

Pelargonium Salmon Fringed was introduced by Messrs. Jarman and Co., Chard, in 1918. It has thick, shiny, leathery leaves, not unlike an Ivy-leaved Pelargonium. The petals are laciniated and of an orange-scarlet colour. The plant is much given to sporting, giving rise to large, flat, pubescent leaves, and flowers that have entire petals, as in an ordinary Zonal Pelargonium. The same thing happens when raised from root-cuttings (Fig. 187). It is interesting to note that Kleiner Liebling, Double New Life and Salmon Fringed, which have imperfect flowers, give normal hermaphrodites from root-cuttings. Sterility in these cases is probably due to chimaerical structure.

REGAL, SHOW OR DECORATIVE PELARGONIUMS.

Many named varieties of these sections of Pelargonium have arisen, both spontaneously and by means of root-propagation from other sorts.

At Merton, the following kinds have given distinct sports from root-cuttings: Pearl, Mrs. Gordon, Don Juan, Escot, Geoffrey Heard, Empress of India, Duchess of Edinburgh, Queen Victoria, and Distinction.

IVY-LEAVED PELARGONIUMS (P. PELTATUM).

L'Elegante, with silvery variegation, and aurea variegata, with golden variegation, both produce green shoots from root-cuttings.

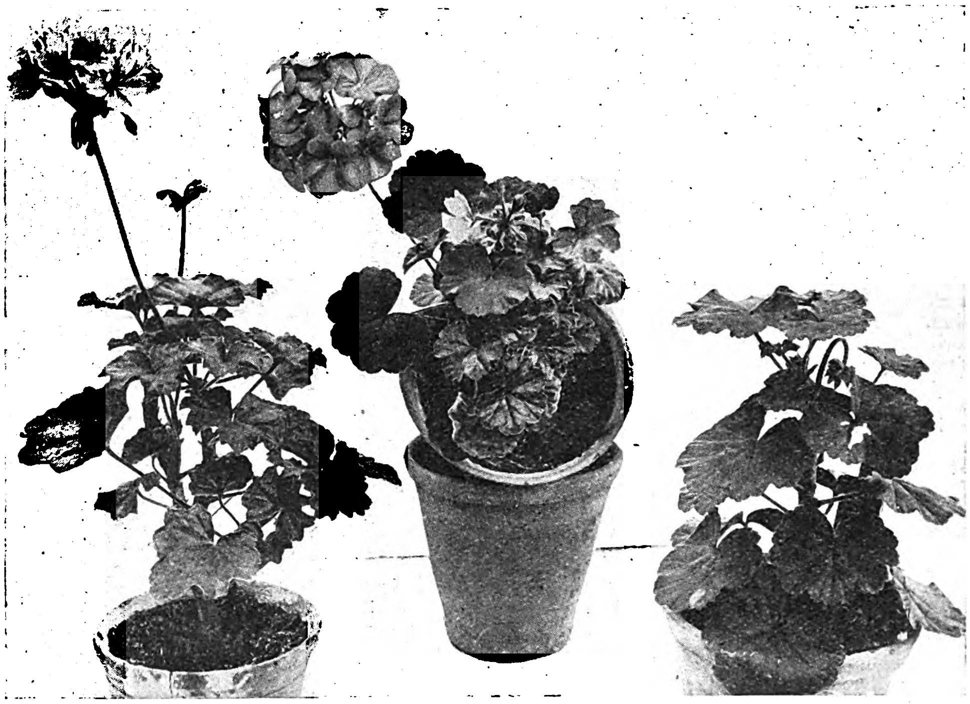

FIG. 187.—PELARGONIUM SALMON FRINGED.

Showing zonale sport (centre), and a similar variation from a root-cutting (right).

Scarlet Crousse sometimes sports a lilac-flowered branch which resembles Jeanne d'Arc.

Generally, the sports of all the foregoing are brighter hued than the parent plant, and sometimes of a distinct colour.

Space will not allow of a full description of these sports here. *A. Hoskings, Garden Superintendent, John Innes Horticultural Institute, Merton, Surrey.*

(To be continued).

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

PROBLEMS OF PLANT LIFE.[*]

XIII.—The Enigma of Dew.

IN periods of drought the attention of the gardener is naturally directed to the action of the dew, and its economy in plant life. The subject, however, is too often studied from a provincial point of view, which leads one to assert that dew rises, another that it falls, and a third that neither of these is right. Those who state that it falls appeal to Aristotle, Wordsworth and others, while those who affirm that it rises claim to rest their contention on observation. The fact is that different people use the term in different senses, and apply it to more than one set of phenomena. In one case the dew falls, in another it results from condensation, while in yet a third case, as yet but little studied, it is spoken of as an underground or internal formation. Modern writers, such as the author of the article on dew in the latest edition of the *Encyclopaedia Britannica*, tend to ignore the historical aspects of the subject, and limit their remarks to the form with which we are more particularly familiar in this country.

The word, however, occurs in the authorised version of the Old Testament about thirty times, and the dew is repeatedly stated to fall. It is called the dew of Heaven (*Genesis*, 27. 28); the clouds are said to drop down dew (*Proverbs*, 3. 20); the hair becomes wet with it (*Canticles*, 5. 2); as did the whole body of the King Nebuchadnezzar (*Daniel*, 4. 33). It forms during the night season (*Numbers*, 11. 9) just as does the dew in our own land, and its effects are similar. We read of a cloud of dew in the heat of harvest (*Isaiah*, 18. 4), and find (*Hosea*, 6. 4) that it vanishes so soon as the sun begins to act upon it. Yet it is evident from the story of Gideon's Fleece that two kinds of dew were known to the Hebrews. This explains how it was possible for the fleece to be dry when all around was moist, and wet when the ground was dry. Dew is deposited in Palestine during the winter when the weather is fine, but in summer and autumn it takes the form of a fine rain, or "Scotch mist." In autumn the westerly breezes are surcharged with moisture taken up from the Mediterranean which condenses when it meets the cooler night air of the land surfaces. When these damp winds reach the uplands, in particular, the moisture assumes the form of a dense mist which is deposited or falls from heaven as dew. Strictly speaking, we might call it rain, but since it serves the same purpose as the dew of our own land, it is not to be wondered at that the translators have used the word dew to represent the original Hebrew word *Tal*. Every recent writer on this subject acknowledges indebtedness to the Rev. James Neil, M.A., for his careful and lucid interpretation of the Scripture dew.[*]

It is to the biblical allusions, therefore, that we owe the idea that the dew falls. When Wordsworth, in his pastoral—the Pet Lamb—tells us that the dew was falling fast, he is following ancient usage and popular tradition. The statement would be untrue if pressed as a scientific fact in English soil, but not if used of one of the lambs of David's flock. But the biblical dew was from the economical standpoint the exact equivalent of the dew which we speak of as rising from the ground in this country. The statement that dew rises is not strictly accurate. Here is Dr. G. C. Simpson's explanation of the physics of dew formation. "On a clear night all bodies radiate more heat than they receive by radiation; and so does the air near the ground. There is therefore a general fall of temperature. If the temperature of the air falls to dew point, mist or fog appears. The fall of temperature of the air, however, is frequently not sufficient for the air itself to reach the dew point; but the temperature of grass and other bodies not in good thermal contact with the ground, falling more rapidly than that of the air, goes well below the dew point. Water then condenses out of the surrounding air directly on the cold body, and dew appears on its surface. The dew is nowhere until it appears on the surface; it therefore neither rises nor falls."

There is, however, a third form of dew the importance of which is only now beginning to be realised by the gardener and agriculturist. In 1913, A. T. Lebedev, published in Russian, a study of the significance of water-vapour in the régime of soil and subsoil water. On this point, in which what is known as underground dew is under consideration, the following quotation from a recent work may be of service. While epiphytes are capable of absorbing moisture by the aerial parts of the plant "other plants are obliged to content themselves with the water supplied by their roots. Dew and light rains, in so far as they only moisten the leaves on the surface of the soil, without penetrating the latter, are probably not directly utilised by our common plants. Matters are different with underground dew, which, in the opinion of many authors, may play a somewhat important rôle in the water supply of desert and even steppe plants. But the question of underground dew is too little elucidated from a purely physical point of view, and is in general too debatable to be dealt with in detail, the more so as the source of the water that enters the zone of attraction of the root system is of no importance to the plant."[†]

This subject of internal dew formation, and its importance to the plants growing on sand dunes and shingle beaches, has received a good deal of attention, as the bibliography appended to the work quoted will show. One remark, however, in the foregoing quotation seems at variance with generally received opinion. Are dews and light rain not directly utilised by our common plants? Is it only by their reaching the roots that they are capable of being used for the refreshment and growth of herb and shrub? It is just possible that here we have been jumping at conclusions, and have assumed that the plants benefit thereby. The crux lies in the words "directly utilize." That the plants drink in the dew to any considerable extent is probably an unproved assumption. But that they are benefited by dew and light rain can hardly be disputed. The benefit, however, lies in the aid which these give to the plant in withstanding heat and drought, assisting transpiration, and avoiding wilting. In this respect it does not signify materially whether the dew is in the form of a mist falling on the vegetation or results from radiation and condensation. We have, apparently, not yet come into full possession of all the facts, and the relation of dew to plant life still calls for fuller investigation. *Hilderic Friend.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.[*]

XXXV.—The Conquest of Polon.

QUARTERMASTER Buttercup now informed me that as the transport had been ready and waiting for several days, and as we had very little food left, we must start for Theronliang at once. Indeed, I had known that we *must* start so soon as I got back from Kaso; that was to be my last climb. It was now October 22, and we were only rationed up to the middle of the month; the Rice, as already explained, had given out a fortnight ago. If the coolies marched everyday, it would take us just a week to reach Theronliang; and in order to reduce the number of loads, we abandoned some of our equipment; we had not food for more than another ten days, and only half the rations at that, and certainly could not afford to spin out the return journey owing to lack of coolie power. Nor could we risk letting our coolie contingent depart, as they were taking us through to the bridge—four stages. Once we reached Chibaon, we anticipated no trouble, as it is a big village, and many of the inhabitants go down to Sadiya in the cold weather; we ought to be able to pick up coolies there to take us on to Denning. As for the lost seeds, well, the alps were now under deep snow which would not melt until next June. Nothing more was to be hoped for from Kaso. But Polon?

It was a brilliant day again, and if ever the weather looked set fair, surely it did now. We spent the whole day sorting, numbering, and wrapping up bundles of Rhododendron capsules, which were to be carried to Sadiya for treatment, since there was no time to catalogue and pack the seeds here. And while we were engaged on this task, I was rapidly forming a resolution, which was, to make one more effort on Polon. There was much less snow here than on Kaso—the peak was about 2,000 feet lower, besides being nearer to the warm air currents from the Lohit valley. But even so, I might get some of the missing plants on Polon, and more seeds of the best plants. We would start the following day, Buttercup taking the kit down the valley, while I and my two Mishmis went on up the ridge to our old camp. The second night I would sleep at the cave, and in the third day climb Polon; I might even spend a second day on Polon. Then, returning down the other side of the mountain, we would go down the valley by forced marches, and probably overtake Buttercup with his coolies before they reached Theronliang; for I reckoned he would be held up a day at Chibaon and probably another day at the bridge.

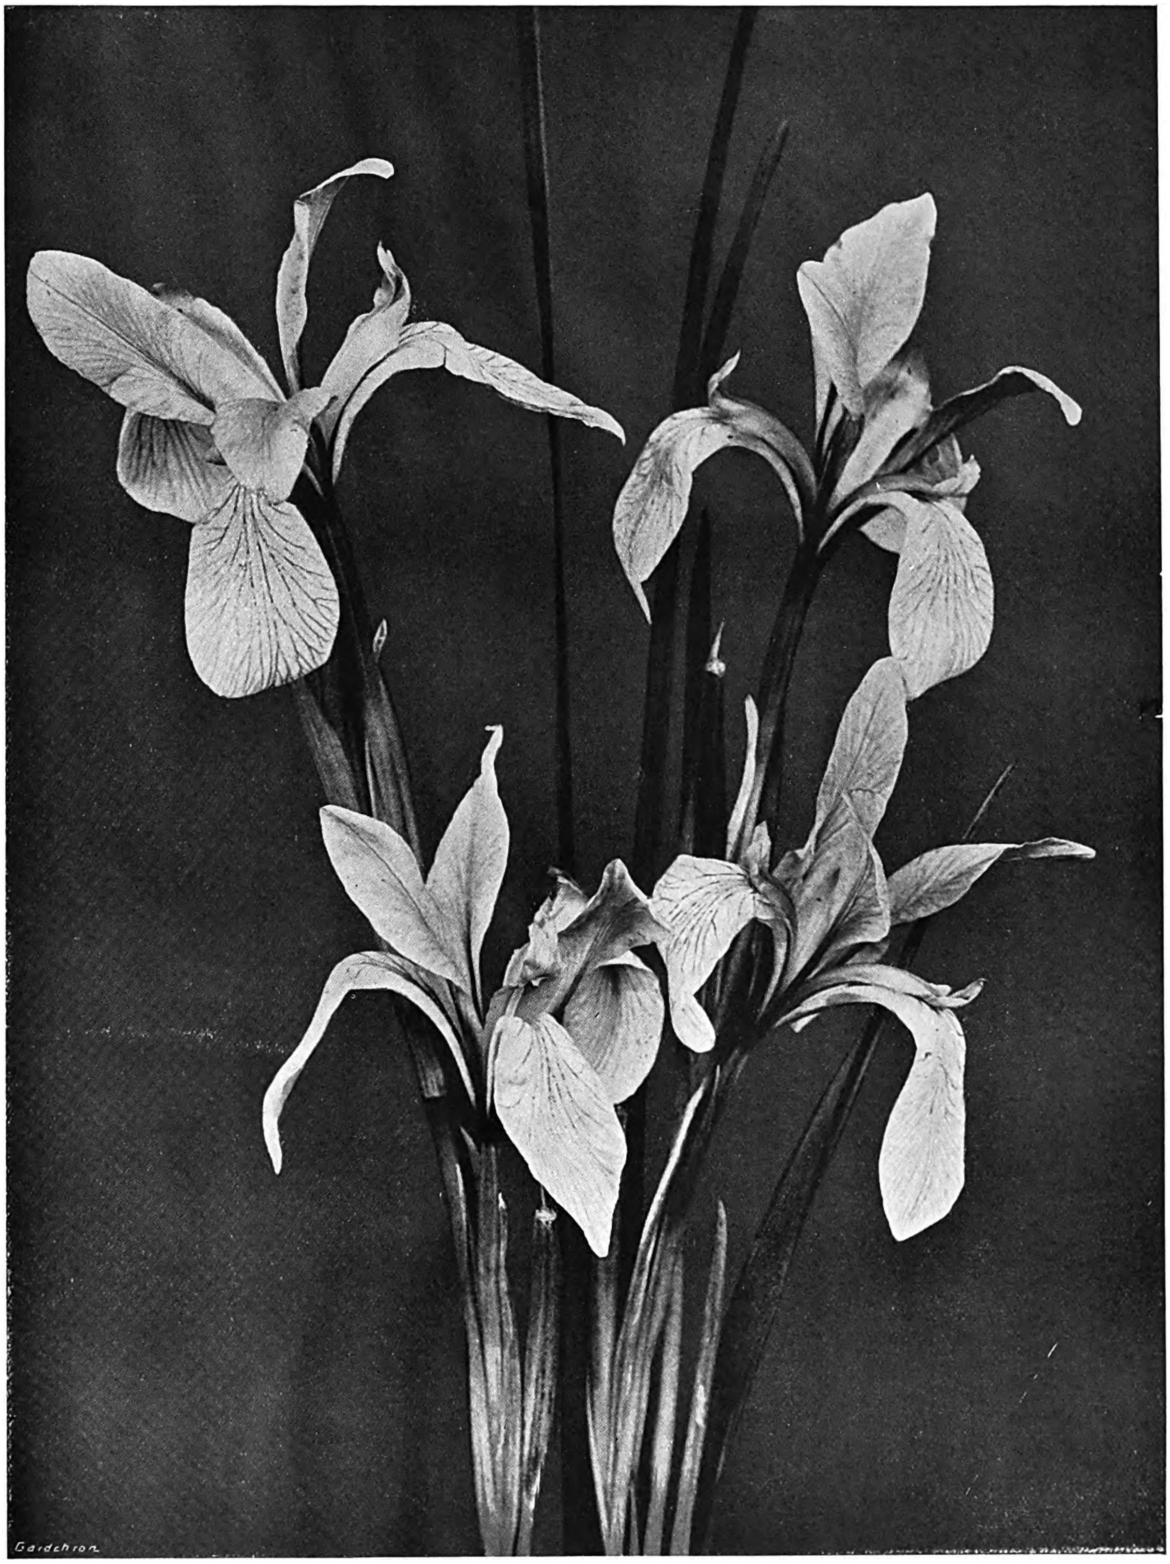
Supplement to THE GARDENERS' CHRONICLE.



IRIS ENSATA.

To this plan Buttercup good naturedly agreed, and I knew that I could rely on him to carry out his part of the arrangement. We started in good time next morning, but the sun shone fiercely as we climbed the thousand-foot face, and we were glad to reach the ridge above and get into the shade. Along the ridge I had a job of work, digging up four species of Phaius. Three of them had leaves so similar that I could not tell them apart, but the fourth—a white-flowered plant, was different, the leaves having a peculiar dull metallic look, as though covered with a film of pewter. The brown one I had marked; and by collecting a sufficient number of the other two, I expected to get both the amethyst and the yellow species. I collected also the Pleione, a plant of the vermilion Aeschynanthus, and various Rhododendron and Hedychium seeds.

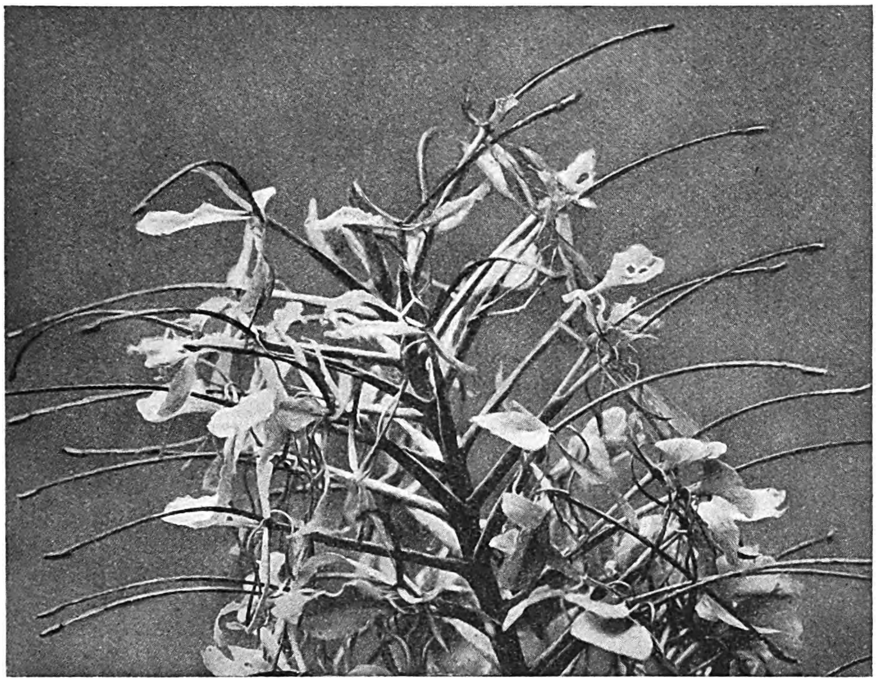


FIG. 188.—HEDYCHIUM SP., K.W. 8,501.

Then we came to the parting of the ways, Buttercup with his coolie corps traversing around the mountain side to Mitonma, while Hubble, the Gam and I went on up the ridge. We reached our late camp at three o'clock. It was a glorious sunny afternoon, and I sat up on the look-out ridge for an hour reading "Moll Flanders." A froth of pale clouds gleamed far away in the south; closer at hand a few wads had laid their heads softly on the frozen tops of the high peaks, as though begging forgiveness for their recent bad behaviour.

The water at this camp was now like stout, without its flavour, and this after three fine days only, so we should have suffered for lack of water had we been in camp here. I sat by a big log fire before turning in, for the first time in months. It was just getting light when I got up. Starting along the ridge before eight o'clock, we made heavy going of the climb, and did not reach the cave until 2.30. The autumn tints along the ridge were very fine, the warm cedar-red of Viburnum, the sharp yellows of the five-pronged Acer and of Rowan, the scarlet of Enkianthus, and the fiery orange of Rhododendron tephropeplum burning hotly against the sombre green of the Fir forest.

Meanwhile clouds had rolled up, and once more the view of Polon from the alpine top was spoilt. This was particularly annoying as I was most anxious to see how deep the snow was. Arrived at the cave, I went off to collect Rhododendron seeds, in the stony glen, where, too, I found a brilliant blue 'Ornata' Gentian on the rocks. Then I dug up some of the ruby-scaled Primula 'bulbs' as an experiment. These 'bulbs,' which are, of course, next year's buds, and only differ from true bulbs in being on, instead of under, the ground, are hard and compact, about as large as Acorns, with long, radiating roots. The bud lies within the crown of the bedraggled dead leaves of the current year, from which also arises the short stem with its cluster of capsules. The capsule differs from the ordinary sausage-shaped parchment capsule of the 'Nivalis' type in being globular and crumbling, a peculiarity it shares, so far as I know, with only two other species, namely P. falcifolia, from Tibet, and P. Agleniana (pink-flowered variety or 'Tea Rose' Primula) from Upper Burma; all three species growing in the very wet mountains of Indo-Himalaya. Having dug up some plants, I cut off the dead leaves, wrapped the buds in dry moss, and within ten days had posted them to England. They were, therefore, less than a month out of the ground; and this is the only way I can conceive of these glorious Primulas ever being seen at home flowering as they flower in the rain-soaked and snow-bound mountains of Indo-Himalaya. For even if they can ever be brought to the flowering stage from seeds—and experience proves how difficult, if not well-nigh impossible, that is—they are certain to perish outright before they are fully developed. The five-flowered plants of this 'Gamboge' Primula for example, and the eight-flowered plants of the 'Tea Rose' Primula, are probably aged six years or thereabouts. P. falcifolia bears only one, or occasionally two flowers. All the afternoon a thin mist was flying up from the valley and the sun was hidden; by nightfall everything was bathed in mist. It looked bad. We were quite comfortable in the cave, warm and dry, but I could not sleep. Every hour I woke up, to see a milk-white veil drawn across the sky; until four o'clock in the morning came. The mist had gone, the stars were shining.

"A fine night, citizens, and all's well!"

In the cold, grey dawn we breakfasted, and then, taking Hubble with me, I set out for the top. Although it was brilliantly fine, the clouds lay thickly in the valley, and as the sun rose, they came rolling up the mountain side; so we climbed fast, collecting seeds as we went along—dwarf Honeysuckle, dwarf Rose, Rhododendron 'Roylei' and, of course, every capsule we saw of the red Primula. We soon reached the ridge, and pushing along towards the summit, found ourselves on sugary snow. Traversing beneath a cliff, I came on scattered plants of the 'Muscarioid' Primula, and fields of the Gamboge 'Nivalis.' A steep climb up a rocky face followed, and we found ourselves on another ridge, making straight for the bare top, in deep snow. Fifteen minutes later, we stood on one of the twin summit peaks, and peeping through the snow were a few clumps of the dwarf 'Anthopogon' Rhododendron. By digging like a badger. I excavated a dozen or so plants, and obtained a few capsules of this beautiful species, whose flowers rival those of R. Williamsianum in their clarity of colour. We descended by a different route, and collected the scarlet, pear-drop fruits of a dwarf Barberry. There were some fine clumps of the blue Gentian here, and I fully expected to find a Meconopsis on the meadow-clad slopes; but I had no luck. The 'Gamboge' Primula grew in wide drifts everywhere—the slopes must have been enveloped in cloth-of-gold in June. The 'Muscarioid' was far less common.

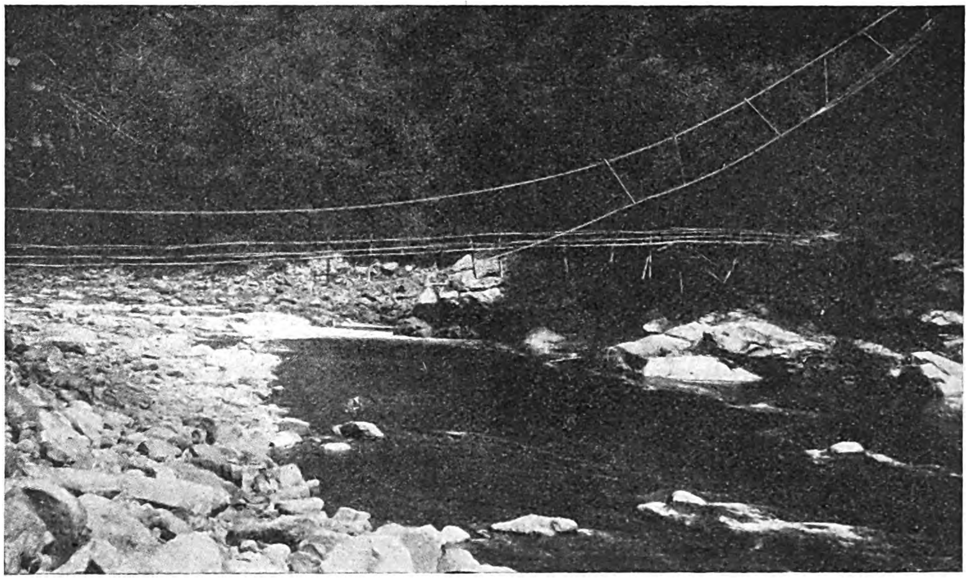

FIG. 189.—THE DELEI VALLEY BRIDGE.

By this time the weather had grown so thick that I could not see where I was going and had to sense my direction. I hit off the ridge, but unluckily, not at the right point, and we did not know whether we were above or below the path, and for the moment we were completely lost. To make matters worse, it now began to snow furiously. We plunged down a gulley, but having descended a thousand feet into the forest, we realised that we were diverging from the path, and must go back on our tracks to the ridge, and start afresh. It was a horrid climb, the rocks now cold and slippery, and the snow blowing in our faces. However, we got back to the ridge; and the mist having thinned a little, we presently made out the path away to our right. Reaching it was more difficult, but we got there at last, thankful not to have been involved in a worse mess. Half-an-hour later we reached the cave, having been nine hours on Polon.

I was quite prepared to tackle the mountain again the following day, but it drizzled all night, and next morning (October 26) the Mishmi Hills were again hidden in the mist, and snow was falling on Polon. I had shot my bolt; there was nothing for it but to return by forced marches. Anyhow, we had got another Primula, the best dwarf Rhododendron, a Barberry, and ample seeds of other good plants.

Immediately after breakfast, we started down the mountain, collecting all the way. In three hours we reached our forest camp, and halted for lunch. Then on down the ridge to Mitonma, where we did not stop a minute, or the Mishmis might have been tempted to murder me. A toilsome march into the deep ravine and up the other side, brought us to a village at dusk; and here we halted for the night, dead beat. *F. Kingdon Ward.*

SOME CHOICE NEW ZEALAND SHRUBS.

Entelea arborescens.

Entelea arborescens, which is probably better known to New Zealanders by the Maori name of Whau, is a comparatively rare, half-hardy plant of great decorative value. Belonging to the Order Tiliaceae, it represents a monotypic genus which is confined to New Zealand, being found in the northern parts of the country and extending south to the Marlborough Sounds in the extreme north-east of the South Island.

It is not a common plant in the wild state, and added to the fact of its rare and local distribution is the fondness of domestic stock and deer for its foliage, consequently the Whau is fast becoming exterminated, except in the uninhabited islets and other inaccessible places, Being a lover of the semi-shade, it is most frequently met with by the edge of forest clearings, growing on the outskirts of lowland forests, or fringing the sea-coast in specially sheltered places.

A small, evergreen tree of tropical aspect, growing to so much as twenty feet in height, bearing bright green, Mulberry-like leaves, four to eight inches long, with toothed edges, and numerous clusters of attractive white flowers, each of which has a conspicuous bunch of yellow stamens, giving the appearance of a yellow eye in the distance, it rarely fails to hold the attention of the most unappreciative observer The beautiful white flowers, each over one inch in diameter, with five delicately crumpled petals, are very abundantly produced in large, terminal and axillary cymes during early summer, that is, from November to January in New Zealand. During the flowering period, both flowers and seed capsules may be found on the same plant. The seed capsules have a very formidable appearance, being provided with stout, rigid bristles or spikes. They are dark brown in colour, and have something of the appearance of a well-armed Chestnut. The young growths, petioles and inflorescences are densely clothed with a covering of soft, spreading hairs.

The tree is comparatively small, rarely exceeding twenty feet in height, but in exposed places it often assumes a shrubby growth-form, in which case six to ten feet is the maximum height attained. The wood is the lightest produced by any New Zealand plant, having about half the specific gravity of cork. The Maoris, recognising the extreme lightness and buoyancy of the wood, used it for the construction of small rafts and floats for their fishing nets.

The Whau is somewhat difficult to raise from cuttings because of the thick mucilaginous sap which exudes rapidly from the severed portion. If this is carefully cleaned off, cuttings taken in early spring will root if inserted around the edge of a six-inch pot full of sandy loam, and placed under a bell-glass in a temperature of 60°. Seeds usually germinate freely, and although young plants are often delicate, they grow rapidly after having passed through the seedling stage. The soft, Begonia-like foliage is very susceptible to frost, and therefore the Whau will respond to treatment similar to that given its near relative, Sparmannia africana.

Ixerba brexioides.

Ixerba brexioides is a very fine tree which has been compared with some of the species of Arbutus for usefulness as a garden plant, because of its graceful habit and pleasing foliage, which make a well-grown specimen a superb feature in any garden, even when the conspicuous clusters of white flowers are not in evidence. It is a monotypic member of the Saxifragaceae, being well-known throughout New Zealand by its Maori name of Tawari. The Tawari has never been a common plant in the wild state, being confined to the northern portion of the North Island, where it is chiefly to be found in mountain woods, attaining its maximum dimensions between sea-level and 2,000 feet. It has been found growing so high up as 3,200 feet, but at that height it becomes stunted in growth, losing much of its attractive appearance. A handsome tree ranging from twenty to fifty feet in height, it bears glossy, dark green, lanceolate leaves four to six inches long, and during November and December it produces a plentiful display of large, waxy-white flowers one-and-a-half inch in diameter, with conspicuous crimson anthers.

This is one of the few plants for whose flowers the Maoris had a special name. They knew these flowers as the Whakou. In pre-European days they followed the almost universal Polynesian custom of weaving garlands of flowers for personal adornment, etc., when celebrating festivals and gala days. Whakou was one of the most popular flowers for this purpose, and garlands made of them were in great demand.

The Tawari is not difficult to cultivate, and may be propagated from either cuttings or seeds. It should be planted in good deep soil, well protected from frost and provided with slight shade. When thoroughly established, it will prove to be one of the gems of any collection.

Clianthus puniceus.

Clianthus puniceus is an easy first as the most gorgeous flowering shrub that New Zealand has produced. It forms a marked contrast to the predominating yellows, whites and greens which go to make the greater portion of New Zealand's indigenous shrubs. This contrast is so very noticeable that various theories have been put forward from time to time to account for the presence in New Zealand of this brilliant member of the Leguminosae.

For many years it was supposed that the Maoris must have brought the plant from some of the neighbouring sub-tropical islands, but we are pleased to know that there is no foundation for this statement, and that Clianthus is a true New Zealander. Evidently it has always been rather a rare plant in New Zealand and seems to have been confined to the north-east of the Dominion. It is now a well-known truth that many New Zealand plants are very limited in their distribution, several, in fact, being confined to one special area, therefore the fact that the Clianthus is of local distribution goes to prove nothing. It was noted by the famous botanists Banks and Solander when they visited the country with Captain Cook in 1769. Solander took specimens to England, where the plant was named, the genus Clianthus being created to receive it. The exact locality from which Solander's material came is apparently rather doubtful, but it is now supposed to have been collected in the East Cape district, where the plant has been known for many years to exist in a semi-wild state, but, unfortunately, is now practically, if not quite, extinct.

Colenso, who arrived in New Zealand in 1834, tells us that he first saw this striking plant blossoming in the missionaries' gardens at the Bay of Islands, the following year, and afterwards he saw it growing apparently in the natural state in some small islands in the Bay of Islands. At the same time, he remarks that during his many years of travel in the North Island he never met with it elsewhere in the wild state, although it was frequently seen adorning Maori villages on the east coast. This early testimony seems to prove that even at that time it was practically extinct, except where it was protected by the Maori people. It would thus appear that this singular flowering shrub has been distributed and probably preserved from extinction by the Maoris, who evidently grew it near their villages because they took a keen delight in the brilliancy of its curious crimson flowers.

It has never been reported from any other country, so evidently was very rare when the Maoris came to New Zealand some five or six centuries ago, and being captivated with the brilliant crimson flowers they cultivated the plant which, fortunately, is very accommodating in its needs. It was probably the only plant of no economic value grown by those primitive people. Even at the present time a few straggling plants may yet be found marking the site of some deserted village. Cattle and deer are all too fond of luscious foliage, and consequently the time is not far distant when this plant will be found only in the cultivated state. The Maoris recognise the flower by its sickle-shaped keel which is narrowed into a long beak, this they termed "Kowhai-ngutu-kaka"—that is, the Kowhai of the Kaka beak, the Kowhai tree being the yellow-flowered Sophora tetraptera. Throughout New Zealand the Clianthus is known as the Kaka Beak or Red Kowhai.

There is an old legend that when the first plants were placed on the British market about 1832, they were rapidly disposed of at £5 a plant.

Clianthus puniceus assumes the growth-form of a drooping herbaceous undershrub varying from three to six feet in height, with prostrate or reclining branches which are more or less covered with a silky down. The branches when in the young state are very succulent, indeed, almost herbaceous. The pinnate leaves are eight or more inches in length, with alternate leaflets in from ten to fourteen pairs. The numerous, bright scarlet flowers are profusely borne in long, pendulous racemes in the axils of the leaves, and, therefore, the plant should be grown on a bank if one is to get the real benefit of its beauty. The fine creamy-white variety, var. alba, which is fairly common under cultivation, comes true from seeds, and consequently there are several good pink forms on the market, all of which are worthy of a place in the garden. They are all comparatively hardy and will withstand up to about 16° of frost, without any ill-effects, but they should be sheltered from anything harder. They present no difficult problems of cultivation, and will flourish in good deep soil in a sunny place, producing a profuson of blossom year after year without fail.

In districts where it is not hardy, Clianthus puniceus may be grown against a sunny wall where some protection can be given during the winter season, or it may be effectively grown in tubs under glass, but it rarely flowers if so treated unless it receives plenty of sun. *A. W. Anderson, Botanic Gardens, Dunedin, N.Z.*

A DIPTEROUS PEST OF BERBERIS AND COTONEASTER SPECIES.

PHAGOCARPUS PERMUNDUS, HARRIS.

DURING the latter part of September, 1928, my attention was drawn to the presence of shrivelled berries on Berberis sibirica by Mr. B. O. Mulligan, Botanical Assistant at the R.H.S. Laboratory, Wisley. On examination, it was found that nearly all the shrivelled berries contained a dipterous larva. A survey of the collection of berried shrubs in the R.H.S. Gardens revealed the presence of similar larvae in the fruits of ten species of Berberis (Fig.190), and two species of Cotoneaster, when so many as eighty per cent. of the fruits on several of these plants were tunnelled by the larvae of Phagocarpus permundus, Harris (Anomoea antica, Weidem.). Larvae collected during the last week in September and the first week in October, 1928, pupated at once, emerging as adult flies from May 18 to 28, 1929. The fly belongs to the family Trypaneidae (Trypetidae), members of which are commonly known as "Fruit Flies." Insects belonging to this family have an extensive cosmopolitan distribution, and to it belong such well-known and destructive pests as the Mediterranean and Cherry Fruit Flies and the Celery and Parsnip Leaf-Miner.

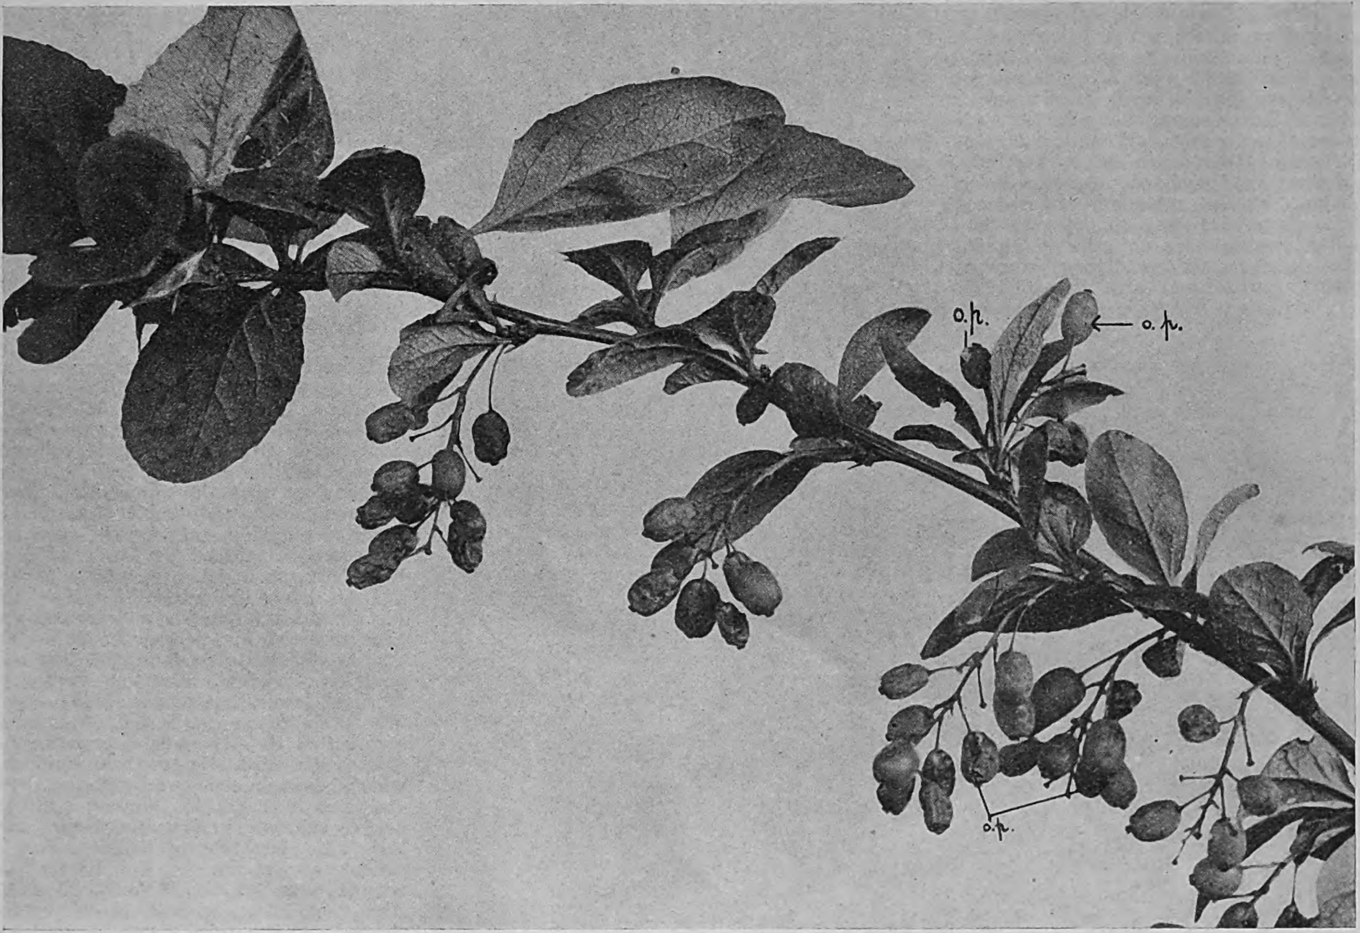

FIG. 190.—BERBERIS KOREANA.

Showing shrivelled berries containing larvae of Phagocarpus permundus and oviposition punctures. (o. p.).

Mr. F. W. Edwards, M.A., of the Natural History Museum at South Kensington, to whom I am indebted for determining the species, informs me that he received a single specimen of the fly taken by Mr. D. E. Kimmins, at Richmond, Surrey, in July, 1929. The only British record was made by Harris[*] in 1776.

DISTRIBUTION.

The British records are scanty and confined to two counties, viz., (i) Kent, in 1776, by Harris, who remarks (*loc. cit.*): "This insect is very scarce, it was found on a leaf near Dartford in Kent"; and (ii) Surrey, by Kimmins, at Richmond, in 1929, and the author, at Wisley, in 1928. One of the recorded continental hosts of this species is Whitethorn, Crataegus Oxyacantha, a statement which may lead one to suppose that this species may have a far wider distribution in this country than the paucity of records suggests. Lindner[*] gives middle and northern Europe and China (Szechuen Province).

HOST PLANTS.

Lindner (*loc. cit.*), quoting von Heyden and Perris, states that the larvae are found in the fruits of Crataegus Oxyacantha, while Handlirsch is stated to have found them in the fruits of Cotoneaster tomentosa. Boie[†] suspects the larvae to feed in the fruits of Pyrus Aucuparia. The recorded host plants at Wisley are confined to two genera, Berberis and Cotoneaster. Among the former, larvae have been taken in the fruits of B. canadensis, B. concinna, B. koreana (Fig. 190), B. Lycium, B. morrisonensis, B. orthobotrys, B. sibirica, B. Thunbergii, B. Vilmorinii and B. virescens, and among the latter, C. divaricata and C. frigida.

DESCRIPTIONS.

The egg has not been discovered as yet in this country. The larva is fairly stout, legless, cream-coloured, tapering towards the anterior end where there is vestigial head. The mouth-parts are reduced to a pair of vertically-moving, chitinous hooks. The anterior spiracles are many-lobed, while the posterior spiracles are provided with three simple slits. There is a pair of rounded anal tubercles. The fully-grown larva is 6 mm. long.

The puparium (Fig. 192) is a firm, oval, corneous case enclosing the pupa. Its colour ranges from cinnamon-brown through shades of brown to light brown, often changing to ivory-white prior to and after the emergence of the adult. It is slightly flattened dorso-ventrally, narrowing sharply both anteriorly and posteriorly. The dividing lines are fairly prominent, allowing nine segments to be seen. The anterior spiracles are prominent and the posterior spiracles are retracted and less prominent. The length is 3½ mm. to 4 mm. and half as broad.

The adult (Fig. 192) has conspicuously-marbled wings with a wing expanse of 9·5 mm. and a body length of 4 mm. The head is clay-yellow, with the upper part brownish and the forehead flat. The antennae are yellowish-brown and three-segmented. The eyes of the living insect are bright green and iridescent. The thorax and scutellum are rusty-yellow to light brownish-red. The back, with the exception of the lateral region and a transverse strip in front of the scutellum, which are reddish-brown, is dusted ashy-grey with three longitudinal lines, the centre one being broader but less distinct. The legs are yellow and moderately covered with hairs. The wings are conspicuously ornamented, especially in the basal area, the top of which is dark brown; there runs from the outer edge of the wing a brown, partly complete loop to the back of the centre of the wing. The abdomen is dark brown with the exception of the first segment, which is paler, and the whole lies densely bristled. The female is provided with an ovipositor by means of which she deposits the egg beneath the skin of the fruit.

[*] *Die Fliegen der Palaeoarktischen Region*, 1927, part 17, pp. 94-95.

[†] *Stett. Ent. Zeitschr.*, Vol. VIII, p. 336.

LIFE HISTORY.

The insect is single-brooded. The female fly tends to make numerous punctures in the fruits by means of her ovipositor, but may only deposit one egg in a single fruit. This frequent puncturing of fruits without oviposition is characteristic of many species of "Fruit Flies." The average number of punctures per berry in Berberis canadensis was 5·36, with a maximum of 10. Only a single larva has been found in any one fruit. The larvae feed on the fleshy pulp or pericarp and may eat into the seeds (Fig. 191). They may be found in the fruits from the beginning of September to mid-October, when they are fully grown. They leave the fruit and enter the soil to a depth of from four to eight inches around the infested bush where pupation takes place. Lindner (*loc. cit.*), quoting Perris, states that the larvae pupate in the fruits. Handlirsch is reported to state that they migrate into the soil. Our observations bear out the latter statement. The pupa is enclosed in a hard, corneous puparium which is highly resistant to the effect of soil insecticides having naphthalene as a base. If infested berries are gathered for seed purposes and kept in boxes, great numbers of puparia are found among the pulp and seeds in the course of a few days. When the infested sample is washed to remove the rotting pulp, the puparia float and may be scooped off with the surface scum. If the seeds are not washed so that the pulp is allowed to dry and then removed by sieving, the puparia are found among the seeds (Fig. 192) and may be unwittingly packeted with them and dispatched to customers, who may overlook their presence.

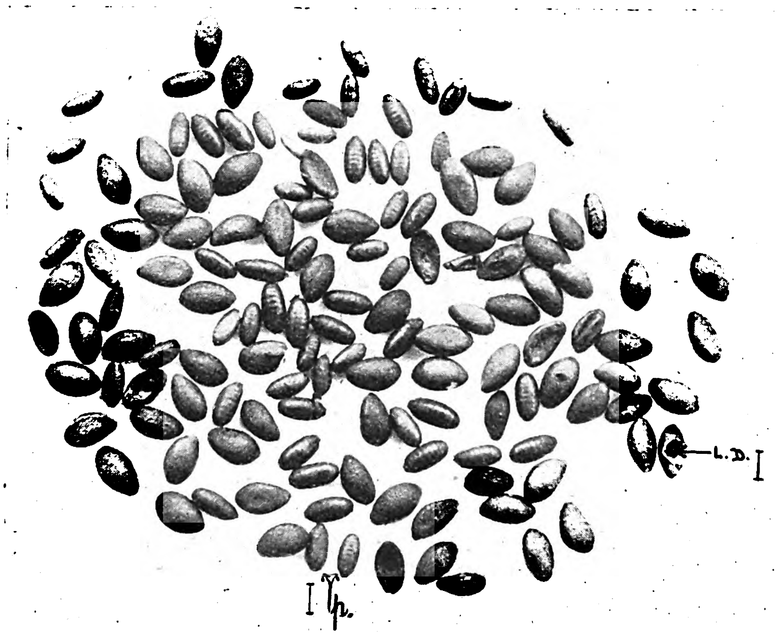

FIG. 191.—SEEDS OF BERBERIS THUNBERGII.
Showing clean seeds; a seed damaged by larva of Phagocarpus (L. D.), and puparia (p.).

The adult flies emerge under natural conditions at the end of June and throughout July.

PREVENTIVE AND REMEDIAL MEASURES.

(1) The use of a deterrent spray, *e.g.*, paraffin emulsion, applied to the developing berries during August will tend to prevent egg deposition.

(2) All shoots bearing numbers of shrivelled berries should be removed and destroyed by fire by the end of September.

(3) Handpicking may be resorted to where the tunnelled berries are few in number.

(4) The removal of surface soil around infested bushes to a depth of at least nine inches should be carried out in December and buried to a depth of two feet, covering the puparia-infested soil with a layer of unslaked lime or watering with cresylic acid emulsion.

(5) The thorough and careful examination of all seed samples and the removal of puparia from them by steeping in water when the puparia and damaged seeds float and may be scooped off with a ladle.

Poison baits and chemically-baited traps are being tried out for this pest, because of the success obtained in the control of many closely allied species of "Fruit Flies" by these methods.

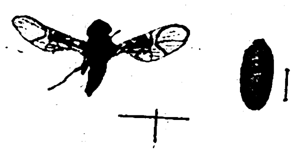

FIG. 192.—PHAGOCARPUS PERMUNDUS ♀ AND PUPARIUM.

My best thanks are due to Mr. Mulligan for directing my attention to the initial attack in 1928, to Mr. Edwards for determining the species, and to Mr. F. C. Brown, of Wisley, for taking the photographs illustrating this article. *G. Fox Wilson, R.H.S. Laboratory, Wisley, Surrey.*

HOME CORRESPONDENCE.

A Large Pumpkin.—A Pumpkin cut here in October turned the scale at nearly five-and-a-half stones (76 lbs., to be accurate), with a girth of five-and-a-half feet, establishing a record for this garden. The extra heat of this summer and a plentiful supply of rain in August may have assisted the fruit in attaining this huge size. Pumpkins have been grown here for the past ten years, but the heaviest hitherto produced was just under 50 lbs. I am not versed in Pumpkin weights, but fancy that fruits upwards of 90 lbs. have been grown in this country, although probably in the warmer south. It is a little surprising that the Pumpkin is not more commonly cultivated, as a change from the Vegetable Marrow. Perhaps one reason against growing it may be summed up in the phrase, "one plant, one Pumpkin"; whereas a Marrow plant usually bears several fruits. This summer we were more fortunate, since from the two plants grown, four other fruits were cut of a manageable size, averaging about 20 lbs. apiece. Size has its disadvantages. The monster one was deposited by the gardener on the scullery floor. The cook asked concernedly what she had to do with it. "Oh, just put it in the larder for the time being," was the reply. "But we can't lift it," she exclaimed. A Pumpkin has more quality in its "flesh" than a Marrow, and can be used (in the culinary sense) either as a vegetable or a fruit. Without resorting to the elaborate ways of dealing with it followed in America, it may make quite a nice filling for a pie when cut up into small pieces and flavoured with Lemon. I am also told by those who have experimented that it makes a better jam than Vegetable Marrow. Pumpkin plants are treated here in exactly the same way as Marrows, and have never missed a summer without giving some return; usually, the whole strength of the plant is concentrated in one fruit. *J. P. Blaithwaite, Wigton, Cumberland.*

Bees and Fruits.—In reply to *F. Akers* (p. 370), it is not possible to state for certain whether in a normal year wasps would have attacked the honey bees, or kept them away from the fruits. Hornets will attack wasps on fruits, and have been seen to kill them and throw the bodies off! It is, however, safe to state that if the wasps had shown signs of molesting the bees the latter would in all probability have got the worst of the argument. *C. Nicholson, Tresillian, Cornwall.*

Helianthemum vulgare var. Mrs. Earle.—In the interesting article on "Plant Variations," by Mr. A. Hosking (p. 323), the author states "Helianthemum vulgare var. Mrs. Earle, double red, often gives a double, yellow-flowered sport called Cumberland Belle." I would like to point out that the name Mrs. Earle, given so frequently to the double crimson Helianthemum, is a modern title applied to it because it had been mentioned by Mrs. Earle in one of her books, as a desirable plant, of which she did not know the name. I believe that lady distributed it fairly freely to friends, and it has thus received her name. It is really an old double variety to be found in lists and works of reference as H. venustum var. plenum, or H. amabile var. flore pleno. Much as one would like to do honour to Mrs. Earle, it is, I think, a pity that the old and proper name should be discarded. With reference to Cumberland Belle, which has been sent out by Messrs. Stormonth and Son, of Kirkbride, Cumberland, it produces double crimson, yellow and bronze flowers on the same plant. A couple of sports from H. venustum var. plenum (Mrs. Earle) originated with the late Mr. P. Hill Normand, of Whitehill, Aberdour, Fife, and were shown by him at a show in Edinburgh, a number of years ago, when Mr. Normand and I discussed them. They were named Jubilee, which is yellow, and Old Gold, bronze, which I see listed as Bronze Jubilee. Rather curiously, although I have grown these for years, none of the three has ever sported. I know nothing about Cumberland Belle in this respect, but it is quite an interesting Helianthemum. *S. Arnott.*

The Need of Education for Gardeners.—I have read with great interest Mr. K. Bell's letter in *The Gardeners' Chronicle* of October 26, and heartily agree with all he writes, but when I find a nobleman advertising for a really clever, first-class head gardener and offering to pay £2 10s. per week, I wonder whether education is valued by an employer. Even making allowance for his house, etc., the remuneration is equal to £4 a week, but there is little possibility of advancement, no retiring pension, and no insurance against unemployment. From personal experience, I know that a head gardener's hours average at least eighty per week, and he has to be as clever in his profession (to be successful) as a lawyer; but can one imagine a lawyer's fee as 1s. an hour! Is it to be wondered then that there is a lack of men who really spend their evenings studying for our profession, especially when a failure with any fancied crop may bring him a month's notice to quit ? With all due respect to Mr. Bell's advice, I think if he were to institute classes for employers where they might learn how a gardener's wife may make ends meet, he would be doing our old profession a heap of good. I also wonder how many of our present day brilliant gardeners who show their skill on the show tables, have, or have had, the time to study up for the N.D.H.; and if they passed the examinations what, if any, financial benefit would they gain ? Empty honours are not very satisfying. *H. Tullett.*

——In your issue of October 26, there appeared an article on the above subject by Mr. M. G. Kennedy-Bell. The time is opportune for such a discussion, when so much is written and said about the losses incurred by those who are engaged in the cultivation of the land both at home and abroad. It is pleasing to see that Mr. William Cuthbertson, with his wide experience of horticultural work, has taken up the mater (p. 371), and it is to be hoped that others with like experience who have given some thought to horticultural education, will come forward and endeavour to rouse all concerned to the need for sound technical training in gardening. Mr. Kennedy-Bell points the way to the young gardener, showing how he can improve his position by devoting his spare time to the study of botany, chemistry, etc.—but how is he to obtain such instruction? In most cases the young gardener lives remote from the large centres where such classes are available, and even where classes in botany and chemistry are within easy reach, the subjects are frequently not taught in such a way as will benefit greatly the young practical gardener. It is true there are some classes available, and, where possible, young gardeners should take full advantage of them. The guidance of an experienced teacher is very necessary in the study of such subjects as botany, geology, bacteriology, entomology, etc. The young gardener is frequently blamed for his apathy towards his studies, but is the fault altogether his ? In many cases the way is not pointed out to him, the head gardener having little interest in him beyond getting his day's work done. There are many exceptions to this. The present writer has known a head gardener attend a class with his six young men, and if he noticed one absent he wanted to know the reason for his absence. If we had more head gardeners of that type we would have more real students of gardening, and the profession would very soon be raised to a much higher level. There are many instructors of gardening nowadays, but do the selection committees always appoint the most suitable men for the posts ? And are they given a free hand to conduct their work in the best interests of the gardener ? In some cases too much emphasis is laid on purely academic qualifications, with the result that the instructor is out of touch with the little practical details which are so essential to interest the young gardener in his studies. I do not for one moment belittle the very highest academic qualifications in a horticultural instructor, but if this is not combined with practical experience, the results are often very disappointing. The competition with picture houses, dance halls, etc., is very great at the present time, but when nature is properly interpreted and attractively presented, as it can be in the hands of a capable horticultural instructor, it can hold its own with such counter attractions, and it has the great advantage of leading the student to a better position in after life. Much has been written for and against examinations, but there must be some kind of test of the student's knowledge of any subject, and if an examination at the end of a course is an incentive to the student to apply himself to his studies, it will have served its purpose, whether he passes or not; although he may not gain a certificate or a prize, he will probably have obtained a fuller knowledge of the subject than he would otherwise have had if the aim of the examination had not always been before him. Although the large private gardens have almost all been given up, public parks and gardens have come into existence all over the country, and, through them, the need for well-trained gardeners remains. There are also many posts, both at home and abroad, open to men who have had a thorough training in horticultural work, and who can specialise in one of its many branches; they have the groundwork of practical experience which is the great asset to the specialist. Much has been done during the past thirty years in providing educational facilities for young gardeners, and they should respond by attending the classes wherever possible, both in the principles underlying their practical work, and in the sciences allied to gardening. Where no classes are available they are generally started if sufficient students are ready to take advantage of them. The young gardener who diligently applies himself to his studies will ultimately get his reward. He should not be discouraged if promotion does not come at once, but should employ the time for further study, and he will then be the better equipped to carry out the responsible duties when his chance arrives. In the meantime, a well educated gardener is almost always held in higher esteem by his employers, and he will also have the satisfaction of knowing that he is assisting in raising his profession to a higher level. The writer has spent over twelve years in evening classes, and can truthfully state that it was the most interesting part of his training. *William Good, Lecturer in Horticulture, West of Scotland Agricultural College, Glasgow.*

Gentiana sino-ornata.—I hardly agree with Mr. S. Arnott (p. 352) when he states that so much has been written in favour of this gem of an alpine that he refrains from writing more. I feel that not nearly enough has been written in its favour, and while contemporaries question its constitution, there will be no encouragement of its increase in popularity. I must, however, endorse his statements that it is such a precious plant that anything affecting its well-being in our gardens is of more than usual importance. I have two batches, one a perfect batch growing in a position where it has no sun whatever, the other planted where it has no protection from the sun, admittedly a poor position. Now it may be interesting to know that where the Gentian is planted in full sun a fungus appeared on the plants, and had a deteriorating effect upon them. The reason for its appearance was, I think, faulty planting; I feel confident that, given its right quarters, namely, a cool and shaded root-run with plenty of peat and sand, G. sino-ornata will resist all disease and thrive. *S. Southgate, Cornhill-on-Tweed, Northumberland.*

Vegetables and Fruits in use in the Eighteenth Century.—Maude Robinson may be pleased to have the following observations on her interesting contribution on the above subject which appeared in *Gard. Chron.*, of November 2, p. 349. Skirrets and Rocamboles are still listed; the former is Sium Sisarum, rather like Salsify, and the latter a Garlic, Allium Scorodoprasum. Finocks is doubtless Finocchio, Fennel, as eaten in Italy. Lazaroles is a corrupt form of the Italian for Medlars. Purslane is also grown nowadays—Portulaca oleracea. *William Lawrence.*

Plant Life and Length of Day.—It was extremely interesting to read your leading article on this subject in the issue for November 2, and although my copy of the R.H.S. *Journal* containing the report of Mr. Tincker's observations has not yet come to hand, it will undoubtedly prove of more than passing interest to most growers. The particular reference in your article as to Chrysanthemums being apparently short-day plants, opens up a question which has occupied the attention of growers for some considerable time, as it is a well-known fact that many varieties of early-flowering Chrysanthemums will open their flowers at least a month earlier in Scotland than they do in the south, although grown under what would appear to be identical conditions otherwise. For instance, with a number of the "Masse" family or group of early-flowering Chrysanthemums, it has been proved by personal experience that in most parts of Scotland there is no difficulty in getting these to flower in time for mid- and the end of August shows, while in the county of Oxfordshire it is nearer the end of September before they are showing colour at all. A friend of mine resident in south Wales, was on a visit to Scotland this year, early in September, and was agreeably surprised to find most of our early-flowering Chrysanthemums in full flower, some of them, indeed, past their first flush of bloom, and he assured me that in and around Swansea none of these varieties was in anything like so advanced a stage, nor was it usual to find them so at the beginning of September. It is also, I think, well-known that in Scotland we have a longer day during the summer months—so much as two to three hours more daylight—and this has been advanced repeatedly to account for the fact that early-flowering Chrysanthemums come into flower so much earlier, but if it is now proved by Mr. Tincker that these are, in reality, "short-day" plants, some other reason will have to be found to explain the matter. I would submit, however, that it is not altogether a question of length of daylight, but a question of the intensity of the light, and anyone who has experienced a really dry period in the south may agree that after six or eight hours strong sunshine most Chrysanthemum plants will be drooping unless supplied with moisture; while in Scotland it is hardly ever necessary to apply water after the plants are established, except in the form of diluted liquid manure. Under these more favourable conditions, and with the extended period of daylight, the plants grow steadily without a check, such as the shorter but more intense sunlight experienced in the south is almost bound to give them, with the results already stated. *A. T. Harrison.*

Calanthes with Flowers and Foliage.—I do not think it is usual for Calanthes to flower while their foliage is almost perfect, but I had the pleasure of seeing a house of these plants under the charge of Mr. T. H. Heron, gardener to I. Haris, Esq., Brackenburgh Towers, Cumberland, all in full flower with almost perfect foliage, and in many cases the leaves were deep green. Some plants of the C. Veitchii section were showing signs of faded foliage, but the strongest bulbs were in fine leafage. This is the first time during a very long gardening career that I have seen Calanthes so flowered. Perhaps other gardeners will state whether they have experienced this combination of flowers and foliage on deciduous Calanthes. *J. C.*

Lonicera nitida.—The sight of an old colleague's name at the foot of a note (p.391) cannot fail to inspire a desire for friendly controversy. Here, in my garden, with hedges of Yew, Hornbeam, Tamarisk, Prunus Pissardi, and all beautiful, easily the best are the hedges, in all some hundreds of yards in length, of Lonicera nitida. It is very pleasant to learn that there are some things which they cannot grow at Wisley—that plant paradise. May I suggest that a liberal dressing of farmyard manure repeated annually for a year or two might help this beautiful plant to hold its own even among the innumerable beauties of the garden at Wisley. Lime L. nitida certainly does not want. It browns a little where it is exposed, and where the exposure is severe it will not do well. A friend who, on my advice, planted it in a Cambridge garden, complained sadly that it would not withstand the polar breezes which made Cambridge such a bracing place in winter. I think it is the dry top soil to which Mr. Chittenden refers that L. nitida abhors. Here it grows in lightish soil in one part of the garden and in heavy ground with a clay subsoil in another part. It is equally happy with either. The severity of last winter left our plants unscathed and serene, and that in the climate of the neighbourhood of Oxford which, although suaver than the climate of Cambridge, has rigours which are unknown to the dwellers at Wisley. No, no, we cannot have aspersions cast on our favourites; my advice is, give it plenty of farmyard manure, and mulch the plant in summer. I advise this with very little confidence, for I have done neither, but, nevertheless, I think the advice worth giving because our soil is old pasture, very rich in all the known and unknown things which conspire to achieve that mystery which we call soil. *F. W. Keeble.*

SOCIETIES.

ROYAL HORTICULTURAL.

November 19.—This fortnightly show, which was held in the Royal Horticultural Hall, Vincent Square, Westminster, was very bright for the season, and of a miscellaneous character. There were several interesting collections of good Orchids, and the Committee recommended one First Class Certificate and four Awards of Merit to novelties. Chrysanthemums were the chief floral feature of the show, while Nepenthes, winter-flowering Begonias and Carnations of merit were also shown. An unusual feature of the show was the vases of Roses which Mr. C. Engelmann had brought from the U.S.A. Two of the varieties and three Chrysanthemums were recommended by the Floral Committee for Awards of Merit. The Walnut competition was an immense success and illustrated the number and diversity of the varieties grown in this country. The Fruit and Vegetable Committee recommended an Award of Merit to a new dessert Apple. There were the usual exhibits of paintings and garden sundries.

Orchid Committee.

Present: Sir Jeremiah Colman, Bt. (in the chair), Mr. Gurney Wilson (Hon. Sec.), Sir Frederick Moore, Mr. Lionel de Rothschild, Colonel Stephenson Clarke, Mr. Fred J. Hanbury, Mr. J. Wilson Potter, Mr. Richard G. Thwaites, Mr. R. Ashton, Mr. J. Cowan, Mr. T. Armstrong, Mr. A. McBean, Mr. J. E. Shill, Mr. Fred K. Sander, Mr. Charles H. Curtis, Mr. H. G. Alexander, Mr. A. Dye, Mr. S. Flory and Mr. H. H. Smith.

First Class Certificate.

Miltonia pulchra var. Lyoth (*M. William Pitt* × *M. Lyceana*).—A very fine hybrid of glowing colour. The wide sepals and petals are rich crimson, with very narrow margins of rose on the latter and on the the tips of the former. Lip very broad, rich crimson, with a light reddish-brown mask that is edged with pale mauve. Shown by Messrs. Charlesworth and Co.

Awards of Merit.

Miltonia Lydia var. Regina (*M. Princess Mary* × *M. Beau Brummel*).—This was represented by a small plant, consequently the flowers were small. The sepals and petals are crimson; the wide lip is white, with a mask and spottings of dark brownish-crimson, but rosy at the margins. Shown by Messrs. Charlesworth and Co.

Potinara Rosita (*Sophro-Laelio-Cattleya langleyensis* × *Brasso-Cattleya Rosita*).—A large-flowered form with lemon-yellow sepals and petals, faintly stained in the centre and at the tips with mauve; the big, frilled lip is light mauve, speckled and edged deeper mauve, and with a wide, orange-veined central area. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Laelio-Cattleya Moloch var. Stromboli (*L.-C. St. Gothard* × *L.-C. Sargon*).—A brilliant, large-flowered variety with ample, deep rose-purple sepals and petals, and a wonderful frilled lip that is vivid, velvety ruby-crimson, with purple margin and base, and a dark, old-gold veined central area. Shown by Messrs. H. G. Alexander, Ltd.

Cypripedium Llancayo (*C. Mrs. Richards* × *unknown var.*).—A bold hybrid with a white-ground dorsal sepal, green at the base, and with numerous large, dark purple spots, often confluent. Petals green and brown, with purple spots; lip green with brownish veining. Shown by R. W. Rickards, Esq. (gr. Mr. H. Luff), Usk Priory, Monmouth.

Groups.

Messrs. Stuart Low and Co. arranged a bright exhibit which had a beautiful background of Oncidium varicosum Rogersii, and good plants of Cattleya Peetersii var. alba, C. Decie var. alba, C. labiata, C. Moira var. The Bride, and C. Fabia immediately in front of it. In the foreground they grouped the curiously-coloured Brasso-Cattleya Maroniris, Oncidium bicallosum. Dendrobium cymbidioides, the tiny-flowered D. nutans, Cymbidium Gamieanum and Maxillaria lepidota.

Messrs. Charlesworth and Co., submitted a group containing fine spikes of Odontoglossum crispum, O. Priapus, O. Princess Yolande, O. grande, Odontonia Etna, O. Aloma, Laelio-Cattleya Medusa, L.-C. Mysia, Sophro-Laelio-Cattleya Senator and other good things.

Messrs. Cowan and Co. showed Cypripediums in good style, with a background of Oncidium crispum and O. varicosum Rogersii. Outstanding Cypripediums were C. T. B. Armstrong, C. insigne, Harefield Hall var., C. Regina var. Seymouriae, C. Praim and C. Royal George.

Messrs. Sanders showed Cattleya Hardyana var. alba, C. President Wilson, C. Snowclad, the old Selenipedium macrochilum var. giganteum, Brasso-Cattleya Ilene var. tenebrosa, Arpophyllum cardinale, Cypripedium Fairrieanum, Saccolabium acutifolium, Bifrenaria aureofulva and other interesting subjects.

Messrs. Black and Flory and Baron Bruno Schröder each showed a few new seedling Orchids.

Floral Committee.

Present: Section A.—Mr. H. B. May (in the chair), Mr. J. M. Bridgeford, Mr. D. B. Crane, Mr. R. Findlay, Mr. C. F. Langdon, Mr. D. Ingamells, Mr. J. T. West, Mr. W. B. Gingell, Mr. G. W. Leak, Mrs. Lindsay Smith, Mr. J. B. Riding and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. C. T. Musgrave (in the chair), Sir W. Lawrence, Bart., Mr. Mark Fenwick, Mr. F. G. Preston, Mr. G. Reuthe, Mr. E. H. Wilding, Mr. C. Williams, Mr. T. W. Taulor, Miss Ellen Willmott, Mr. W. B. Cranfield, Mr. L. R. Russell, Mr. R. C. Notcutt, Mr. T. Hay, Mr. R. Cory, Hon. H. D. McLaren and Mr. N. K. Gould, Secretary.

Awards of Merit.

Chrysanthemum Hebe.—See National Chrysanthemum Society's Awards, page 392. Shown by Mr. H. Shoesmith, junr.

Chrysanthemum Yellow Monument. — See N.C.S. Awards, p. 392. Shown by Mr. T. Stevenson.

Chrysanthemum Sundown.—A medium to large Single variety made up of several rows of crimson-maroon ray florets with a small disc. Shown by Mr. H. Woolman.

Rose Autumn.—A very pretty H.T. variety of medium size. The centres of the blooms were of rich golden-yellow colour suffused with bronze and surrounded by velvety-rose-coloured outer petals. The leaves were dark green and somewhat suggestive of a Pernetiana origin. The stems were densely set with small thorns.

Rose President Hoover.—This showy H.T. Rose has much longer stems and slightly paler green leaves than the previous variety. It is also a well-formed variety of medium size and variable colouring, which may be described as shades of pink with outer petals of much deeper colouring. The two Roses, and a third variety, a deep crimsom H.T. named Mrs Herbert Hoover, were shown by Mr. C. Engelmann, who had brought them, packed in an unopened box, from Murray Hill, New Jersey, U.S.A., where they were cut on November 8. As the boxes had been unopened and the flowers had developed in the dark, their normal colours may not be the same as described above.

Groups.

Near the gallery, Messrs. L. R. Russell, Ltd., had an exceedingly interesting collection of twenty-three distinct Nepenthes. Not only were the plants especially well-grown and furnished with good typical "pitchers," but with the aid of plants of Cissus discolor and a ground-work of Maranta regalis and other sorts it made a very attractive exhibit. The principal Nepenthes were N. Sir William Thiselton-Dyer, N. Hookeriana, N. ventricosa, N. Russelliana, N. mixta, N. Mastersii, N. Lewis Bradbury, N. paradicea, N. Tiveyii and N. formosa. Mr. John G. Romer showed half-a-dozen well-grown plants of Begonia Rex varieties from a small, unheated greenhouse in Sandycombe Road, Kew Gardens, Surrey.

Among the plants which did not receive an award were Cyclamen Rohlfsianum, a species from Grenna and Italian North Africa. The large mottled leaves are very attractive and the plant also bears lilac-coloured floweres of perfect Cyclamen shape. It was shown by W. Van de Weyer, Esq., Clyffe, Dorchester. E. M. Preston, Esq., The Warren House, Hayes, Kent, showed a small plant of Staphylea gigantea bearing a splendid flower.

Excellent collections of greenhouse Carnations were staged by Messrs. C. Engelmann, Ltd., and Messrs. Stuart Low and Co. The former had good vases of Laddie, Spectrum, Rouge, Chintz, Maine Sunshine and Jazz. Messrs. Stuart Low and Co. showed, in Ann Horton. and R. A. Nicholson, two of their novelties of considerable merit. The former is a delicately beautiful Fancy, while R. A. Nicholson is a vivid scarlet-cerise bloom. Other good Fancies in this collection were Sheila Greer, Sunny, Daphne and Butterfly.

An imposing group of winter-flowering Begonias was set up by J. Pierpont Morgan, Esq. (gr. Mr. Steward), Well Hall, Hertfordshire, in association with equally well-grown plants of Gesnera chromatella and small Palms. The chief Begonias were Clibran's Pink and Altrincham Pink, two good doubles; Exquisite, a large single rose-shaded flower; Conquest, clear salmon-pink, and Eclipse, scarlet. An effective display of Statice profusa superba with white Carnations and Chrysanthemums was made by the Rolvenden Nurseries. Mr. G. Zambra had a good collection of Sweet Violets. The chief varieties were Princess of Wales, Princess Mary and Governor V. Herrick. Messrs. Blackmore and Langdon staged a collection of greenhouse Cyclamen of good useful types. The Misses Hopkins set out an attractive miniature moraine.

A handsome group of particularly well-grown Chrysanthemums was set up with their usual skill and taste by Messrs. H. J. Jones, Ltd. The exhibition varieties were represented by Lancashire, Hugh Mitchell, Mrs. Gilbert Drabble, W. Rigby and Red Majestic of large size and perfect form. The dainty little Pompons were especially well shown, and the varieties included Baby, Golden Climax, Primrose League and Snowdrop. There were also many Singles and Decorative varieties.

In the exhibit of Messrs. Keith Luxford and Co. the large exhibition varieties were represented by a golden-yellow seedling, Nottingham, Madame M. Stirling and Dresil. The chief Singles were Incomparable, Sonia, Absolute, Crimson Velvet and Daphne, while among the Decorative type were good vases of Balcombe Beauty and Baldock Crimson.

An attractive group of market type Chrysanthemums was displayed by Mr. A. G. Vinten. The Singles were especially meritorious, and these included Enid, Daphne, G. Fox Wilson, Sandown Radiance and Susan. Among the Decorative sorts were Alice Honeur, Balcombe Pink, Queen of Pinks and Ra.

A valuable collection of water-colour paintings of garden flowers was shown by the Rt. Hon. Sir Herbert Maxwell, Bart., Monreith, Wigtonshire. This included many Rhododendrons, Fritillarias, Buddleia globosa, Mutisia decurrens, Anchusa italica, Berberidopsis corallina, Abutilon vitifolium and Lavatera Olbia. Other exhibitors were Miss Lilian Forsyth, Mrs. T. H. Gibbard, Miss Gladys Thomasset, Mr. Lawrence Perugini, Mrs. A. C. Fowkes, Mr. V. F. P. Thompson and Violet Fawkes. There was also a very faithful little collection of Orchid paintings, made for the late Sir Trevor Lawrence.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. W. H. Divers, Mr. G. Kelf, Mr. H. Prince, Mr. J. Wilson, Mr. E. Neal, Mr. W. F. Giles, Mr. E. Beckett, Mr. G. F. Tinley, Mr. A. Bullock, Mr. P. A. Tucker and Mr. A. N. Rawes, Secretary.

Award of Merit.

Apple Woolbrook Pippin.—A very good seedling from Cox's Orange Pippin, shown by Messrs. Stevens and Sons, Woolbrook Nurseries, Sidmouth, Devonshire. The fruit is flattened conical in shape, with a fairly large, open eye set in a shallow basin, the short stalk being set in a deep, rather narrow cavity. The ground colour is primrose-yellow, but this is mostly hidden by the bright red flush, which makes the fruit of very attractive appearance; the stalk cavity is russeted. The flesh is firm and crisp, and the flavour rich and sweet. An Apple with a future.

The Walnut Competition.

The object of this competition was to discover good varieties among the many seedling Walnuts throughout the country, and judging by the enormous number exhibited, considerable success in this respect was achieved by those responsible for the organising of it, chief among these being Mr. Howard Spence, a recognised authority on Walnuts, who conducted the preliminary examination of the nuts and also assisted in the final judging.

There were two classes for Walnuts, open to all, one for fresh nuts and the other for dried nuts, 3 lbs. gathered from one tree being required. In the two classes there were 732 entries, and a vast range in size, form, general appearance, thickness of shell and quality of kernel was portrayed.

In Class 1, E. K. Ransell, Esq., Ixworth, Suffolk, was first, with a dish of nuts of medium size, thin shelled, and with full, clean kernels. J. Plowman, Esq., Coldcroft Farm, Huntley, was second, showing thin-shelled, oval fruits with large kernels.

This latter exhibitor was first in Class 2, A. E. Wraight, Esq., Faversham, being second, with clean Walnuts, oblong-oval in shape, thin-shelled, and with large, full kernels.

The Cobnut and Filbert Competitions were disappointing. In the amateurs' section there were only three exhibits of one dish of Kentish Cob, and the first prize only was awarded, this going to E. M. Chambers, Esq., Greenhill House, Otham, Kent. D. W. Berkett, Esq., (gr. Mr. W. Waglen), Blagden House, Trowbridge, showed the best dish of any Filbert or Cobnut other than Kentish Cob, the second prize being awarded to Lord Harlech (gr. Mr. Back), Brogyntyn, Oswestry.

In the Market Grower's section, Messrs. Thornton, Skinner and Co., Leeds, Kent, shared the first prize for the best half-sieve of Kentish Cob, packed for market, with Mrs. Burgess, Moons Farm, East Farleigh, Maidstone, the second prize being awarded to H. G. Chambers, Esq., Greenhill, Otham, Kent.

Groups.

An extremely interesting exhibit of illustrations and specimens of Walnuts grafted on roots of Juglans nigra by the "Treyve System," was set up by M. L. Treyve, Trevoux, France, who also showed specimens of fruits of various Walnuts and Butternuts, Juglans species, Platycaryas and Caryas, embracing over one-hundred-and-forty examples in all.

The California Walnut Growers' Association showed fruits of four varieties of Walnuts —the pick of those grown in America; these were Diamond Large Eurekas, with large, long nuts, well-filled with clean kernels; Diamond Large Paynes, with big, rounded fruits, very fine; Diamond Large Budded, with slightly smaller nuts than the preceding and thicker-shelled; and Diamond Large Mayettes, the nuts of which are about the same size as the preceding but with thinner shells and large, clean kernels.

A good deal of work has been carried out at East Malling Research Station recently in connection with Walnut propagation, and already much valuable information concerning the suitability of various stocks and methods of grafting has been obtained, so that the splendid exhibit from this station demonstrating Walnut propagation was of special interest.

The exhibit was set up in sections. Nuts of the species tried as stocks, namely, Juglans regia, J. nigra, J. californica, J. cordiformis, J. cinerea, J. Royal (hybrid) and J. Paradox (hybrid) were shown, and the method of stratifying Walnuts to preserve them for sowing in the open in March was demonstrated. One-year-old and two-year-old specimens of species suitable for grafting were shown, but layers are found to be better as stocks, being more uniform in growth, as seedlings show considerable variation. Layered plants of J. regia (English in preference to Himalayan), have been found most suitable as stocks for Walnuts in this country; in America, seedlings of the Royal and Paradox hybrids are at present much favoured, although layering does not appear to have been tried in that country yet. Grafting on to Pterocarya caucasica and P. sinensis, closely related to Juglans, is not recommended, as although union was quick, after-growth was very poor.

The various methods of grafting were demonstrated. Greenwood grafting under glass during July and August is recommended as a cheap method of securing stock for nurserymen, and this method gives one-hundred per cent. "take"; grafting under glass in February and March gives good results also, seventy to one-hundred per cent. of the grafts being successful. The double-tongue graft is employed, and paraffin wax is used for covering the graft. Top-grafting of headed-back old trees was also demonstrated. Specimens of various grafted trees were shown, small grafted trees in four-and-a-half inch pots being recommended as most suitable for dispatch to distant countries, as these allow for economy of cost and transport and when planted grow away freely. The whole exhibit was one of extreme interest, staged with the thoroughness associated with the East Malling Research Station.

Messrs. Shearns, the well-known purveyors of fruits and flowers, showed an interesting collection of magnificent Walnuts.

GUILDFORD CHRYSANTHEMUM.

The reputation of this Society for staging a good show was well maintained in the Thirty-seventh Annual Exhibition held on November 6 and 7. There was keen competition in all classes, and fine collections of flowers, fruits and vegetables were to be seen in both amateur and trade groups, while Messrs. Fogwill, of Guildford, made quite an artistic display of many varieties of Potatos and a few Onions.

Conspicuous among prize-winners was The President of the Society. From his gardens at Cross Lanes he staged twelve exhibits. These were awarded eight first and four second prizes. Mr. Smallpeice readily passes on the honour of this creditable achievement to Mr. W. Binfield, his gardener.

A notable feature was the class for Singles, which occupied almost one side of the large hall, and presented a dazzling mass of flowers. The first prize exhibit in this class contained an extraordinarily good collection of blooms and was an example of well-nigh perfect staging.

Among the exhibits of Apples, the winning dishes of Peasgood's Nonesuch and Bramley's Seedling were of exceptional merit; these were shown by Mortimer Menpes, Esq., of Pangbourne. The Bramley's Seedlings carried the prize for the heaviest dish in the show.

The exhibition, which drew a large attendance each day, is held in the largest available hall in the town, but is handicapped for lack of space. F. F. Smallpiece, Esq. (gr. Mr. W. Binfield), was first for a group of Single Chrysanthemums; for six vases of Single Chrysanthemums (not disbudded); for twelve Japanese blooms, distinct; for six Japanese blooms, one variety, on boards; for six incurved blooms, one variety; and for six Incurved blooms, distinct. The best collection of Chrysanthemums in pots was from Mrs. Paynter (gr. Mr. H. Cook), while in a similar class, limited to amateurs and single-handed gardeners, Mr. W. Bullen was first.

E. F. Wheeler, Esq. (gr. Mr. A. Simmons), was a successful exhibitor in the Japanese Chrysanthemum classes, gaining first prizes for eighteen Japanese blooms, no fewer than twelve varieties; eighteen Japanese blooms in six varieties; and for nine Japanese blooms, any varieties. Neil Gassage, Esq. (gr. Mr. H. Huntley), showed the best six vases of Single Chrysanthemums, disbudded; and Messrs. Bond were first for six Japanese blooms, distinct. Neil Gassage, Esq., showed the leading six specimen Chrysanthemum plants, his best being a grand specimen of Golden Seal.

In the fruit classes, Mrs. Hansard led for two bunches of black Grapes, and for white Grapes; M. Menpes, Esq., staged the best six dishes of Apples and Earl Beatty the best twelve dishes; Col. Warburton was first for two dishes of Pears, distinct.

The best collection of vegetables, nine sorts, was Earl Beatty's.

NATIONAL CHRYSANTHEMUM.

Fifteen new Chrysanthemums were placed before the Floral Committee at the meeting held in the new Horticultural Hall, on Monday, November 18. The following awards were made.

First Class Certificates.

Viscountess Hambledon. V.1. a.—A large-sized, Single variety of rich crimson colour, with a narrow yellow zone around the disk. Shown by Mr. W. H. Turnham, Greenlands Gardens, Henley.

C. G. Weston. II.2.b. A beautiful golden-yellow Incurved Japanese variety, very fine disbudded, and excellent in spray form, but in the latter condition it loses its Incurving style and assumes a slightly deeper gold tint. Should prove a very useful decorative and market variety. Shown by Messrs. Cragg, Harrison and Cragg.

Sundown. V.1.a.—A very large Single variety of good exhibition style. The colouring is deep ruby-crimson, with a golden centre.

Desert Song. V.1.a.—Another very big Single variety with broad florets of reddish-bronze hue, tipped with gold.

Trent. II.1.a.—This is a fine, white Japanese variety of exhibition size and form; it is deeply built and has broad, loosely curling outer florets. These three varieties were shown by Mr. H. Woolman.

LLANISHEN AND LISVANE CHRYSANTHEMUM.

This Society held its first show in the Wesley Hall, Llanishen, on November 15. It was a wonderful exhibition of exquisite blooms and well-grown plants, and great credit is due to the organisers of what appears to be the leading Chrysanthemum show in the Cardiff and South Wales district.

A luncheon was held at the Church Inn, over which Major J. G. Gaskell, the President, presided, and among others who attended were Douglas Cory, Esq., W. G. Gunstone, Esq., Mr. W. Bennett (Chairman), Mr. W. H. Pryce (Treasurer), Mr. Th. H. Morgan (Secretary), and the judges, Mr. H. R. Farmer and Mr. M. Trye, who said they were surprised and pleased with the quality of the flowers.

A special feature of the exhibition was the class for berried sprays and coloured foliage, the prizes for which were given by Alan Gibbs, Esq. This class was well represented and went to show the material available for embellishing gardens in late autumn.

The classes for fruits and vegetables were well filled, and the colour of the Apples and Pears was remarkably good. A very attractive non-competitive exhibit of Begonia Gloire de Lorraine and other subjects was arranged by Sir William Thomas's gardener.

Among the chief first prize winners were E. M. Hann, Esq., Alan Gibbs, Esq., Major Gaskell, D. Cory, Esq., G. E. Turner, Esq., Gilbert Robertson, Esq., W. North Lewis, Esq., E. A. Purser, Esq., Mrs. Morgan Lewis, Mr. J. Haines, Mr. G. H. Mullins, Miss F. Willey, Mr. G. H. Pryce, Mr. M. C. Kirby, Mr. W. Clarke, Mr. A. Stone and Mr. John Rees. For the best bloom in the show, Mr. W. H. Pryce, gardener to Major J. G. Gaskell, was awarded the prize for a remarkably fine specimen of Mrs. Algernon Davis.

BIRMINGHAM CHRYSANTHEMUM.

November 12, 13 and 14.—The sixty-fifth Annual Show, held in the world-famous Bingley Hall, Birmingham, was a great success. The Show Committee keeps abreast of the changing times, making the schedule representative and attractive to exhibitors by introducing new classes and offering good cash prizes. It was very gratifying to hear so many complimentary remarks about the character, variety and all-round quality of the show, which is one of the biggest and best outside London. So numerous were the exhibits of Chrysanthemums and honorary displays that the great gallery around the hall had to be requisitioned for the competitive vegetable classes.

Cut Blooms.

The principal new class, which it was hoped would appeal to some of the best exhibitors in the country was a success, and although only three exhibits were placed before the judges, each showed high culture and artistic arrangement. The schedule required cut blooms representing so many types or forms of the Chrysanthemum as possible, arranged on a ground space of fifteen feet by six feet, to face one way, and all stands, vases and receptacles had to rest on the ground. Cut foliage and plants (but not Codiaeums) were allowed. The object of this new class is to demonstrate the varied character and adaptability of the Chrysanthemum for different purposes. The first prize, a Silver Challenge Cup presented by the proprietors of *Amateur Gardening*, supplemented by £15 by the Society—was won by Mr. H. Woolman, Shirley, Birmingham, whose handsome display included specimens of Mrs. Algernon Davis, Hugh Mitchell, Mr. T. W. Pockett, Birmingham, Queen Mary, Aquitania, Yellow Majestic, Louisa Pockett, Thames and Avon. Incurved, Single, Pompon and Anemone-flowered sections were represented by choice varieties. The second prize exhibit, which came from the King's Acre Nurseries, was remarkable for some beautiful flowers of Birmingham, J. Symonds, Yellow Majestic, Charles Davis, Miss J. Moore, Edith Dymond, Daphne, White Model and Ondine. Third, Messrs. Clement Dally and Co.

The President's prize of £5 was again offered for a group of Single Chrysanthemums. Here again, Mr. H. Woolman won the first prize with uncommonly large flowers of Kirkland's Crimson, Fantasy, Yellow Mona, H. Shoebridge, Susan, Mrs. W. J. Godfrey, Golden Seal, R. Andrews, Lady Aileen and Mrs. E. Hudd; second, Mrs. Guthrie (gr. Mr. P. Burr), Northampton, who showed big, well-coloured specimens of Sandown Radiance, Edith Dymond and Golden Seal.

The class for thirty-six Japanese Chrysanthemums in not fewer than eighteen varieties and not more than three blooms of any one variety, each flower in a separate vase, had four very good entries. The first prize, which consisted of a Silver Challenge Shield and £15, was won by the Dowager Lady Annaly (gr. Mr. D. Cameron), Holdenby House, Northampton, whose flowers were of regular size and beautifully fresh. Varieties of outstanding merit included Miss Ada Ellis, Norman Chittenden, Yellow Majestic, Red Majestic (premier flower in the show), Julia, Mrs. K. Luxford, Victory, W. Rigby, Queen Mary, Ajax and Mrs. Gilbert Drabble. Colonel Gretton (gr. Mr. A. Graham), Melton Mowbray, last year's winner, was a close second. His flowers were rather bigger than those of the first prize-winner, but not so fresh nor so even; third, Mr. H. H. Tomlinson, Derby, whose display included grand flowers of several good sorts.

The best nine vases of Japanese Chrysanthemums, in three varieties, one bloom in a vase, came from G. L. Waller, Esq. (gr. Mr. E. Avery), Finstall Park, Bromsgrove, who had beautiful examples of Cissie Brunton, Mr. T. W. Pockett and Red Majestic; second, Mrs. Rees-Mogg (gr. Mr. C. Hebbourn), Stratford-on-Avon, with clean, fresh specimens of Princess Mary, Mrs. Gilbert Drabble and Majestic; third, the Dowager Lady Annaly.

The first prize for twelve Japanese Chrysanthemums, in not fewer than nine varieties, one bloom in a vase, was won by Mrs. G. Rees-Mogg, with large, well set up blooms over a ground work of autumn-tinted foliage. The following varieties were of outstanding merit, viz., Mrs. Gilbert Drabble, Princess Mary, Red Majestic, Mrs. George Monro, Birmingham and Queen Mary; G. L. Waller, Esq. (gr. Mr. E. Avery), was second; and Viscount Cobham (gr. Mr. J. H. Roberts), Hagley Hall, Stourbridge, third.

In the class for three vases of a pink-coloured Japanese Chrysanthemum, the first prize was won by G. L. Waller, Esq., with handsome examples of Mrs. T. W. Pockett; second, C. Terry, Esq. (gr. Mr. J. Hart), Redditch, with General Petain; third, Colonel Gretton. The best three blooms of a crimson-coloured Japanese Chrysanthemum were contributed by the Dowager Lady Annaly, who staged richly-coloured specimens of Birmingham; second, Mrs. L. W. Wade (gr. Mr. R. H. Rogers), Kenilworth, with Mrs. A. Holden; while of the nine entries in the class for three white Japanese Chrysanthemums, G. L. Waller, Esq., excelled with magnificent blooms of Cissie Brunton, with Major S. J. Thompson (gr. Mr. J. White), Wolverhampton, second, showing Mrs. Gilbert Drabble. C. Terry, Esq. (gr. Mr. J. Hart), took the lead in the class for three blooms of a yellow Japanese Chrysanthemum, with Mrs. R. C. Pulling in extra fine condition; G. L. Waller, Esq., was second. The best three vases of any coloured Japanese Chrysanthemum, except those specified above, were exhibited by Mrs. Rees-Mogg, who had beautiful specimens of Majestic. The Dowager Lady Annaly was second, with Red Majestic, and Colonel Gretton, third, with Julia.

For half-a-dozen varieties of Single Chrysanthemums, six blooms in a vase, Mrs. Guthrie was placed first with beautifully fresh vases of Golden Seal, Susan, Molly Godfrey, Robert Collins, Reginald Godfrey and Mrs. W. J. Godfrey; second, Mr. J. G. Jenkins, Berkswell whose best flowers were Susan Golden Seal and Edith Dymond; third, the Dowager Lady Annaly.

The first prize exhibit of six varieties of Decorative Chrysanthemums, six blooms of each, came from Mrs. Guthrie, who showed Freda Bedford, Monument, In Memoriam and Swardeston White; Mr. E. J. Keeling, Small Heath, Birmingham, was second, his set including good vases of Iolanthe and a promising unnamed seedling from Romance. Colonel Gretton was the leading exhibitor of one vase of nine Single Chrysanthemums, one bloom on a stem. He had large, richly-coloured flowers of Edith Dymond pleasingly arranged with intensely coloured Oak sprays and Selaginella; second, Mr. J. G. Jenkins, with Susan; third, Mrs. Guthrie.

There were three splendid exhibits in a new class for twelve Japanese Chrysanthemums in distinct varieties, open only to members of the National Chrysanthemum Society. The first prize included £3 and a Silver Medal, and the winning exhibitor was the Dowager Lady Annaly, her set including magnificent flowers of Queen Mary, General Petain, Miss Ada Ellis, Red Majestic and Mrs. R. C. Pulling; second, Mr. H. H. Tomlinson; third, J. C. Hill, Esq. (gr. Mr. A. Bennett), Kidderminster.

Local Classes.

In the class for twelve Japanese Chrysanthemums, J. W. Moore, Esq. (gr. Mr. F. Moorman), King's Norton, took the lead with heavy blooms of Mrs. T. Slack, Mona, Majestic, Mrs. R. C. Pulling, Mrs. George Monro, Mrs. B. Carpenter and Victory; second, Major F. C. Hughes, Sutton Coldfield; third, Councillor F. W. Daniels (gr. Mr. W. G. Prosser), Edgbaston. In a class for twelve Japanese Chrysanthemums grown within five miles of Birmingham, F. Jefferson, Esq. (gr. Mr. C. Horton), Edgbaston, excelled, W. Rigby, Mrs. A. Holden, Mrs. B. Carpenter and Mr. T. W. Pockett being the pick of his really good set. Mr. F. J. Lucas, Bearwood, was second, with very creditable blooms. The best two vases of Japanese Chrysanthemums, three blooms of each variety, was shown by Mr. T. Blower, Perry Barr, who had large well-finished specimens of Shirley Golden and William Turner; second, Major F. C. Hughes. Mr. T. Blower also took the lead in a similar class reserved for growers residing within five miles of Birmingham.

F. Jefferson, Esq., was awarded first prizes for (1) two vases of Incurved Chrysanthemums, with Romance and Frank Trestian, and (2) for three vases of Single Chrysanthemums in three varieties, six stems of each, showing Mrs. Harry Woolman, Susan and Red Molly. The only entry in the class for three vases of disbudded Chrysanthemums was from Mr. E. J. Keeling, but the one for six vases of disbudded Single Chrysanthemums made a splendid show, with Mr. J. G. Jenkins, first, and Mr. E. Powell, Bearwood, second.

Table Decorations.

Table Decorations were not so good or so numerous as in some previous years. Of the eight tables decorated with Chrysanthemums, the best was that arranged by Mrs. F. W. Hickton, Belbrighton, being a charming combination of yellow and bronze-coloured flowers relieved with slender sprays of intensely coloured Ampelopsis Veitchii and Selaginella; second, Mrs. W. E. Ball, Metchley Park, Harborne, with crimson Decorative and yellow Single varieties; third, Mrs. S. Warren, Handsworth.

In the next class, in which any flowers could be shown in bowls or vases, Mr. W. H. Hall, Northfield, was placed first with pink Carnations; Mrs. E. Reynolds, Clavendon, second, with red Carnations; and Mrs. W. E. Ball, third, with pink Single Chrysanthemums. The class for a basket of Chrysanthemums made a splendid show, and the first prize was deservedly awarded to Miss M. L. Bailey, Berkswell, for a very artistically arranged exhibit; second, Mr. E. J. Keeling; third, Mrs. F. W. Hickton.

Special Chrysanthemum Classes.

Mr. H. Woolman, Shirley, Birmingham, offered prizes in the three following classes: (1) for nine Japanese Chrysanthemums: first, Mr. H. H. Tomlinson, whose flowers of Princess Mary, Mrs. A. Holden, Queen Mary and W. Rigby were of superior merit; second, Mr. J. G. Jenkins; (2) for six Japanese Chrysanthemums on boards: first, Mr. H. H. Tomlinson, with Mr. John Allen, Old Hill, second; and (3) for twelve Japanese Chrysanthemums; first, The Dowager Lady Annaly, with G. L. Waller, Esq., second.

Mr. H. Woolman also offered a guinea for the best Japanese Chrysanthemum in the show (trade excluded), and this was won by the Dowager Lady Annaly, with Red Majestic.

Miscellaneous Plants.

First prizes in classes for (1) twelve pots of Begonia Gloire de Lorraine, and (2) six pots of Begonia Gloire de Lorraine, were won by Viscount Cobham, with medium-sized specimens covered with flowers. G. L. Waller, Esq. (gr. Mr. E. Avery), showed the winning set of twelve Cyclamens; and T. Andrews, Esq. (gr. Mr. W. A. Wait), Lichfield, scored in the class for six Cyclamens. The last-named exhibitor secured first prizes for (1) three Palms, and (2) one Palm.

The half-a-dozen scarlet Salvias that gained first prize for J. W. Moore, Esq. (gr. Mr. F. Moorman), King's Norton, were particularly good, being dwarf, bushy and smothered with long racemes of flowers. The Earl of Plymouth (gr. Mr. F. Molyneux), Hewell Grange, Redditch, sent the leading set of six Primula sinensis. G. L. Waller, Esq., won the first prize for six Primula obconica; his plants carried richly-coloured flowers. The Dowager Lady Annaly beat T. Andrews, Esq. (gr. Mr. W. A. Wait) in a class for six table plants. Messrs. Clibrans offered prizes for six pots of Cyclamens, which were won by G. L. Waller, Esq., and the Earl of Plymouth, first and second respectively.

Fruits.

The Studley Horticultural College was the only exhibitor in a class for a collection of British-grown fruits, on a table space of fourteen feet by four feet, and the first prize of £10 was deservedly awarded to it for an attractive exhibit which included black and white Grapes, Apples, Pears, Melons, Quinces and Coe's Golden Drop Plums.

Mr. C. W. Powell, Wareham, Hereford, won first prizes for single dishes of Apples Allington Pippin, Bramley's Seedling, Hambling's Seedling, King of the Pippins and Rival. Mr. H. Wallhead, Leamington, had the best dish of Bismarck, and C. L. Phillips Powell, Esq., Llyswen, Brecon, led with Annie Elizabeth; and in a class for any dessert variety not mentioned in the schedule, showing shapely fruits of Herrin's Pippin. Miss Avis M. Powell, Llyswen, had the winning dishes of Blenheim Pippin and Lane's Prince Albert. Miss E. M. Powell, Boughrood, won first prizes for dishes of Cox's Orange Pippin, Cox's Pomona, Charles Ross, James Grieve, Lord Derby, Newton Wonder, Peasgood's Nonesuch, The Queen and Warner's King, as well as in another class for a culinary variety not named in the schedule.

Canon Lea, Droitwich, was first with lovely-coloured specimens of Gascoyne's Scarlet, and Miss E. M. Powell won the first prize for three dishes of culinary Apples.

The Bishop of Lichfield (gr. Mr. J. G. Knight), Stafford, had the best dish of Beurré Diel Pear, and he also beat nine contestants in the class for any Pear not recognised in the schedule. He showed exceptionally good examples of Marie Louise.

H. G. Bois, Esq. (gr. Mr. A. E. Moss), Alcester, took the lead with Pear Durondeau, and Miss E. M. Powell exhibited the best Doyenné du Comice. F. J. J. Gibbons, Esq., was successful with Emile d'Heyst and Canon Lea won the first prize for Pitmaston Duchess.

There were six first-rate exhibits in the class for three bunches of black Grapes. The Studley Horticultural College was first, with shapely bunches of Alicante; second, the Dowager Lady Annaly. Lady Bird (gr. Mr. R. Bennett), Solihull, excelled in the class for three bunches of white Muscat Grapes with handsome bunches of Muscat of Alexandria; second, the Studley Horticultural College, with Canon Hall Muscat.

Competition was strong in the local classes for (1) two dishes of kitchen Apples, and in another for two dishes of dessert Apples. Mr. W. Payne, Marston Grange, won both first prizes with large, handsome fruits, and Mr. C. G. Compton took second prize in each class.

Vegetables.

Vegetables were shown in splendid condition and competition was better than usual. H. G. Bois, Esq. (gr. Mr. A. E. Moss), Alcester, won first prizes for (1) six varieties of Potatos, and (2) twenty yellow Shallots. Major Harcourt Webb (gr. Mr. W. Gaiger), Spring Grove, Bewdley, was successful in classes for (1) nine Onions; (2) six Carrots; (3) six Leeks; and (4) six Parsnips.

Mr. C. Nix, Bournville, had the best round Beet, and Canon Lea excelled with long Beet. Mr. A. H. Hickman, Cookley, Kidderminster, was first with Celery. Mr. W. Hall led in the Cauliflower class, and in another for Savoys. Mr. E. J. Keeling won with red Pickling Cabbages, and Mr. F. Cartwright, Kidderminster, with Brussels Sprouts. Mr. S. G. Fathers, King's Heath, showed the best red Shallots, and Mr. E. B. Preater, Moseley, had the winning dishes of (1) round Potatos, and (2) kidney Potatos.

Honorary Exhibits.

Large Gold Medals were awarded to Messrs. Gunn and Sons, for Roses and Box trees; Mr. John Cock, for Potatos; Mr. H. Woolman, for Chrysanthemums and floral designs; Messrs. Bakers for a floral display, dried flowers, and shrubs; Messrs. D. Stewart and Sons, for shrubs and alpine plants; Mr. F. A. Godfrey, for an ornamental garden; the King's Acre Nurseries, for Chrysanthemums and fruits; Messrs. J. and W. Green, for Chrysanthemums; and Messrs. P. and F. Smith, for an ornamental garden.

Small Gold Medals were awarded to Messrs. Allwood Bros., for Carnations; Messrs. Hewitt and Co., for a floral display; Messrs. Clement Dally and Co., for vegetables; the Forest and Orchard Nursery Co., for fruits and hardy trees; and Mr. R. Scott, for hardy shrubs.

Silver-gilt Medals were awarded to Messrs. Hopwood and Sons, for fruits; Messrs. Blackmore and Langdon, for Cyclamens; the Bournville Village Nurseries, for fruits and shrubs; and Mr. F. Rich, for Chrysanthemums, Cyclamen and Primulas.

A Silver Medal was awarded to Miss S. S. Thompson, for Cacti.

Obituary.

Frederick Hanson.—For nearly forty years gardener to the Crossley family at Somerleyton Hall, Suffolk, Mr. Frederick Hanson passed away on November 1, at a nursing home at Norwich. Mr. Hanson was sixty-eight years of age, and during his long period of service at Somerleyton he not only maintained, but enhanced, the horticultural features of this fine garden, famous among other things for its large winter garden. His relations with his employers were of the most cordial character, as shown by Major the Hon. Francis Crossley's observation, "Not only have we lost a splendid servant, but also a fine friend." At the funeral at Somerleyton Church, there was ample evidence of the deep affection and great respect in which Mr. Hanson was held by the members of the various East Anglian horticultural societies, horticulturists in many parts of the county, Lord and Lady Somerleyton, and other members of the Crossley family.

Charles E. Pearson, V.M.H.—The news of the sudden and tragic death of Mr. Charles E. Pearson came as a great shock to us, as he was in his usual good spirits when we were chatting to him on the occasion of the National Chrysanthemum Society's Show, at Westminster, a few days ago. One of the three brothers who have for so many years conducted the business of Messrs. J. R. Pearson and Sons, Lowdham, Mr. Charles E. Pearson concerned himself chiefly with florists' flowers and hardy plants, particularly during the latter part of the firm's tenure at Chilwell; in those days he was a skilful and extensive cultivator of Chrysanthemums, Pelargoniums and Fuchsias. A man of unbounded energy, he was amazingly cheerful, despite the disability of deafness which had, unfortunately, increased in recent years, and was the primary cause of his tragic end. On the 14th instant, when on his way to Nottingham, and while his daughter went to the booking office at Lowdham, he set out to cross to the opposite platform by the level-crossing. The gates were closed against the public, and there was a dense fog, so Mr. Pearson neither saw nor heard the approach of a train; the engine struck him and he sustained such severe injuries that he never regained consciousness, and passed away at his home, Hillcrest, on the following day. As Secretary of the Horticultural Trades Association—which he founded—for a score of years, and as Editor of the *Horticultural Advertiser*, founded by himself and Mr. Alfred H. Pearson, V.M.H., Mr. Charles E. Pearson did a vast amount of work for the horticultural industry. Despite his seventy-three years, he continued young in spirit and outlook, and few people knew his age. To the last he was a sportsman, and although he had to give up hockey some years ago, he continued to play tennis, and last winter he skated like a man of half his years. Our friend—and we have enjoyed his friendship for nearly half-a-century—had one great hobby, and that was the collection of birds' eggs, indeed, he was a well-known ornithologist, and visited Norway, Nova Zembla, Algeria, and many European countries in pursuit of his hobby. A widow, one son and two daughters mourn the loss of a husband and father who greatly loved his home and family; we offer them our deepest sympathy. One son was killed in the war; the other, Mr. Aubrey Pearson was badly damaged in the conflict, but survived, and is now in charge of the firm's seed farm at Marks Tey. Mr. Charles E. Pearson led a full and useful life and made hosts of friends in this country and on the Continent, all of whom will deeply deplore the death of such an upright, cheerful and able business gentleman. He was awarded the Victoria Medal of Honour in Horticulture in 1924, and for a long period of years he was a member of the R.H.S. Floral Committee, and a regular attendant at the R.H.S. meetings, usually coming from Lowdham, fulfilling his duties as Committeeman, reporting the show, and returning home on the same day. A portrait and appreciation of Mr. C. E. Pearson appeared in *The Gardeners' Chronicle* of April 11, 1925.

Thomas S. Simpson.—Born at Peebles, Scotland, in 1884, Mr. Thomas S. Simpson served his apprenticeship at Stobo Castle, and passed on to Whittinghame, under Mr. Garrett, and thence to Drumlanrig, under Mr. David Thompson. He served as foreman at Hopetoun for one year, and for five-and-a-half years as foreman under Mr. Hunter, at Lambton Castle. For many years he was head gardener to F. S. H. Dyer-Bennet, Esq., at Stourton Court, Stourbridge. After the sale of Stourton, he took charge of Glemham Hall Gardens, Wickham Market, Suffolk, for the Earl of Guildford. During his service at Glemham he received every encouragement from Lord Guildford, and carried out extensive improvements there. He was also a keen competitor at Woodbridge Floral Fêtes, and won many prizes for both plants and fruits, particularly Grapes. When Glemham was sold he took charge of the beautiful Newstead Abbey Gardens, Nottinghamshire, under Sir Charles Markham; and when Lady Markham gave up Newstead, he became gardener at The Cliff, Warwick, the property of Sir Michael Laken, Bart. He retired in July, 1929, and went to live with his youngest son at Warsop Vale. He passed away after a brief illness on October 9, and was buried at Warsop, on October 11, among numerous floral tributes from former employers and many friends.

ANSWERS TO CORRESPONDENTS.

Cyclamen Corm Diseased.—*A. C.* Your parcel had burst open in transit, and the Cyclamen corm had disappeared from the box in which it was sent.

Gladioli not Flowering.—*W. K.* The Gladioli corms and foliage are healthy and free from attack by any pathogenic organism. The reason for the absence of flowers this season is due to the planting of immature corms in spring. Unless mature flowering corms are planted only leaves will be produced.

Grubs in Ground.—*J. A. G.* If you gave us some idea, or sent specimens, of the pest you are troubled with, we might be able to assist you better. A good dressing of quicklime should prove beneficial if dug into the soil.

Names of Plants.—*H. T.* 1, Picea orientalis; 2, Taxus baccata; 3, Viburnum Tinus (Laurustinus); 4 Prunus Laurocerasus (Laurel); 5, Cupressus Lawsoniana var. Allumii; 6, Cotoneaster horizontalis; 7, Taxus baccata var. fastigiata; 8, Cupressus Lawsoniana var. erecta viridis; 9, C. Lawsoniana; 10, C. obtusa; 11, Osmanthus Delavayi; 12, Salix sp.; 13, Veronica cupressoides; 14, Lysimachia Nummularia; 15, Veronica prostrata; 16, Acaena microphylla; 17, Acaena Sanguisorbae; 18, Cerastium tomentosum; 19, Muehlenbeckia complexa.—*N. C. C. C.* Gaultheria pyroloides.—*H. R. G.* Eucomis punctata.—*C. H.* 1, Phyllocactus, please send in flower; 2, Mamillaria gracilis; 3, Erysimum cheiranthoides; 4, Eupatorium riparium; 5, Crassula portulacea; 6, Impatiens Sultanii; 7, Acanthopanax rincifolium; 8, Abutilon, please send in flower.

MARKETS.

COVENT GARDEN, Tuesday, November 19, 1929.

WE cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in the day.—EDS.

REMARKS.—No doubt the unfavourable weather conditions during the past week were responsible for the general slackness throughout this department. Roses and best Carnations maintained their prices, and these blooms may become more valuable during the next few days. Liliums were firmer in price this morning. Chrysanthemums are still too numerous for present requirements, and only the best disbudded blooms and spray varieties meet with any demand; the most prominent sorts, disbudded, are Chieftain, Cheshunt White, Favourite and Monarch, with such coloured varieties as A. Brooker, Ivy Gay, Choco, Golden Glory, Liverpool Yellow, Romance, December Bronze, December Gold, Market Red and R. F. Felton. Single Chrysanthemums still retain their excellent quality, the disbudded varieties being exceptionally fine in quality, especially White Mensa, Bronze Absolute, Golden Absolute, Golden Seal, J. H. Blyth, Exmouth Pink and Jessica, and the spray varieties are the best so far offered this season. Violets appear to be on the up grade this morning, but all other lines are similar to last week's quotations. In the French department supplies are increasing almost daily and all blooms are arriving in better condition. They now include single Violets, Anemone De Caen, Ranunculus, Carmine and Barbarou—also some very fine scarlet and orange Romanos, with white and yellow Narcissi, yellow Marguerites and Marigolds. There is also a good variety of foliage, and Carnations, but there is little demand for the latter.

REMARKS.—Trade in the fruit market is about normal for November, practically all sections reporting a weak demand. The Apple market in particular is depressed. there being a lack of movement of either English or imported Apples. The English section is being overloaded with a lot of second-grade fruits which are selling slowly at very low money, and the figures ruling for Apples from the United States are also poor. The hothouse Grapes department is receiving moderate supplies of Grapes, both from Holland and Belgium, as well as home-grown, and values are fairly steady. A sprinkling of English Doyenné du Comice Pears is available, but unless really good, these do not sell freely. Guernsey is sending some good hothouse Beans and a few Peas, both of which sell well, although prices are rather high. Some new Potatos from Guernsey, however, are difficult to sell at good prices. There are still some excellent English Tomatos coming on the market, but the competition of Tomatos from the Canary Islands is such that second-grade old crop English sell with some difficulty. Mushrooms continue a firm trade and go out freely each day. Cucumbers are still a firm market and show a further increase in price. Cauliflowers from Cornwall and St. Malo are popular and selling freely. Salads have increased in supply from France and sell well. Root crops are a slow trade, and the Potato section remains steady.

GLASGOW.

The cut flower market again developed weakness during the past week, where prices of Chrysanthemums reached the lowest levels of the season. Sprays ranged from 1d. to 6d. each, while disbudded blooms sold as follows:—Ada Brooker, 4s. per dozen (loose); 1s. 6d. for 6's, and 2s. 3d. to 2s. 6d. for 12's; In Memoriam, Pink Chieftain and Mason's Bronze, 1s. 3d. to 1s. 6d. for 6's; Phyllis Cooper and Golden Seal, 1s. to 1s. 6d.; Jean Pattison, 8d. to 1s. 3d.; Cranfordia, 9d. to 1s.; Pink Profusion, Rose Maid and Florrie King, 8d. to 1s.; W. H. Thorpe, 6d. to 1s.; Almirante and Le Pactole, 8d. to 10d.; Sandown Radiance and Blanche de Poitou, 6d. to 10d. Carnations varied from 1s. 6d. to 3s. 6d. per dozen; Roses, 3s. 6d. to 4s. 6d.; Richardias, 2s. to 4s. 6d. per bunch; Lily-of-the-Valley, 1s. 6d.; and Violets, 3s. to 6s. per dozen bunches.

In the fruit market American Apples further declined in value. Cox's Orange Pippin sold at 22s. to 25s. per case; McIntosh Red, 13s. 6d. to 14s. 6d.; Grime's Golden, fancy, 13s. 6d.; Jonathan, 12s. 6d. to 15s.; York Imperial, 25s. 6d. per barrel. Winter Nelis Pears, Block brand, realised 23s.; Washington, 17s. 6d.; South African Oranges, 150's, 25s.; Grape Fruits, 80's, 96's and 112's, 25s.; Malaya Lemons, 420's, 25s 6d.; Almeria Grapes, 14s. to 22s. per barrel; Pineapples, 4s. 6d. each; Muscat Grapes, 4s. 6d.; Gros Colmar, 3s. 6d.; Alicante, 2s. 6d. and Black Hamburgh, 2s. per lb.

A feature of the vegetable market was the early arrival of Guernsey Potatos, which realised 8d. to 1s. per lb. Scotch Lettuces made 2s. to 2s. 6d. per dozen; Cauliflowers 5s. 6d.; Guernsey Beans, 1s. 3d. box; Brussels Sprouts, 5s perhalf-pot; Mushrooms, 2s. 6d. to 3s. per lb.; field produce 2s. 10d. per chip.

WEATHER IN OCTOBER.

Under a very unusually disturbed, and frequently low, barometer, this was a month of exceptionally westerly winds, the scarcity of north-easterly, easterly and south-easterly winds being notable. A substantial rainfall was experienced, the drought being effectually terminated. No less than three-quarters of the total precipitation, however, occurred during twelve hours extending from 11 p.m. to 11 a.m.; hardly any rain fell between 1 p.m. and 4 p.m. Yet, for some obscure reason, the forenoons were more sunny than the afternoons. A wet and windy month, it was brighter than many dry and calm, but therefore hazy ones. Nor was it cold. The mean temperature was 49·9°, or 0·7° above the average; while the daily range was much below normal. There were 109 hours of bright sunshine, or an excess of 12 hours. Rain fell in measurable amounts on 26 days, or eight more than the average; the total quantity in Hesketh Park was 4·52 inches, or 0·81 inch above the local normal. Hail was reported on four days; gales on three days (but "whole-gale" force was not reached at Southport); and lightning and thunder on one day (the 25th). Ground frost was registered on five nights. A very decided rise took place in the level of the underground water. *Joseph Baxendell, The Fernley Observatory, Southport.*

GARDENING APPOINTMENTS.

Mr. Albert Webb, for the past three years gardener to LADY LEWIS, The Grange, Rottingdean, and previously for five years to the Rt. Hon. LORD ORMATHWAITE, Warfield Park, Bracknell, as gardener to the Hon. A. HOWARD, Wappingthorne, Steyning, Sussex. [Thanks for 2s. 6d. for R.G.O.F. Box.—EDS.]

Mr. J. D. McKinnon, for the past three years gardener at Dunsmore, Rugby, as gardener to Colonel L. H. HANBURY, C.M.G., Hitcham House, Burnham, Bucks

Mr. George R. Clayton, for the past five years gardener to Major J. D. BARNSDALE, Lynton Hall, Nottinghamshire, as gardener to Captain the Hon. GERALD PORTMAN, Healing Manor, Lincolnshire. [Thanks for 2s. for R.G.O.F. Box.—EDS.]

Mr. E. Wooldridge, for three years gardener to the late F. H. DRUCE, Esq., Woking, and previously for twelve years to Captain H. S. STOKES, Longdon, Rugeley, Staffordshire, as gardener to Sir CHARLES McLEOD, Bart, Woolton Hill, Newbury. [Thanks for 2s. for R.G.O.F. Box.—EDS.]

Mr. W. Wyatt, for the past fourteen months gardener to Commander C. W. MEYNELL, R.N., Burcote Brookse Abingdon, and previously for three years at Burcot, House, Abingdon, as gardener to STUART PAUL, Esq. Freston Lodge, near Ipswich. [Thanks for 2s. for R.G.O.F. Box.—EDS.]

Mr. E. R. Johnson, for nineteen years gardener to A. HEPBURN, Esq., Stone House, Reigate, as gardener to Sir CHARLES EVE, Chestnut Lodge, Horsham, Sussex. [Thanks for 2s. 6d. for R.G.O.F. Box.—EDS.]

The Genetics of the Rose.

THE National Rose Society has rendered a valuable service to horticulture in reprinting the paper read at the International Rose Conference in July, 1928, by Major Hurst, on the Genetics of the Rose.* For it is only by close attention and repeated reading that the ordinary man not conversant with the recent rapid developments of genetical science can hope to grasp the arguments used in this most important paper. It is well worth the while of everyone interested in the breeding of plants or in the science of horticulture to study Major Hurst's work with care, for anyone who does so may begin to realise that a time is coming and that shortly when our present vagueness with respect to the nature of species will give place to precise knowledge. Already Major Hurst is prepared to tell us how many of six-hundred-and-seventy-four species, sub-species, varieties and hybrids of the genus Rosa are related one with another. The magic staff which enables the geneticist to work such wonders is, of course, the microscope. By its aid the rods or blobs constant in form and number of which the nucleus of the plant cell is composed may be seen and counted and their behaviour observed. These essential ingredients of the nucleus, the chromosomes, carry in orderly manner all those things of unknown nature which call forth the characters which distinguish one plant from another. Each one of these so called factors is responsible for some character or other—size, habit of growth, shape of leaf, kind and colour of flower, presence of stipules, hairs; no matter how small nor how great the character may be, it owes its existence to some substance carried in a definite fixed part of one or other of the chromosomes. No wonder therefore that the chromosomes of plants and animals have been and are still being subjected to the closest examination; for if current theory be true, they hide and will ultimately reveal the secrets of heredity of man and beast and flower. To follow Major Hursts account of the Genetics of the Rose it is necessary to realise that just as any cell of a plant owes its origin to the fusion of a male and a female reproductive cell, so each chromosome of a body cell is of dual nature—a paired structure, one-half of which comes from the male cell and the other half from the female cell. In the cell division which leads up to the formation of reproductive cells the halves of each chromosome separate and one half of each goes into the nucleus of one of the reproductive cells, and the other into the other. When reproduction takes place pairing of like chromosomes occurs, and hence the nucleus of the body cell appears to have double as many chromosomes as did the male or female reproductive cell which contributed to its formation. Major Hurst gives an interesting illustration of these general facts; Rosa multiflora, a Japanese Rose, has tall, summer-flowering stems, and single, white flowers. Rosa chinensis is a Chinese Rose with dwarf, perpetual-flowering stems and semi-double pink flowers. Each of these Roses has seven pairs of chromosomes in its body cells, and seven single chromosomes in its germ cells. Now other experiments have shown that the factor or gene for tall-flowering summer stems is located in a certain one of the seven chromosomes; the factor or gene for single flowers happens to be located in a second chromosome, and the gene for white flowers is located in a third chromosome. And so also it is in Rosa chinensis, for the corresponding three characters each is dependent on a gene or factor located in a given chromosome. Call these three chromosomes 1, 2 and 3. Chromosome 1 of R. multiflora mates in fertilisation with its opposite number, chromosome 1 of R. chinensis, and so in each nucleus of every body cell the paired 1-1 chromosomes carry in one half the gene for tall-flowering stems, and in the other half that for dwarf perpetual-flowering stems. The gene for tall dominates that for dwarf and the hybrid is tall, with summer-flowering stems. So, doubtless, chromosome 2 carries in one half the gene for single, and in the other half the gene for doubleness; a compromise results—the hybrid has semi-double flowers. So again, since chromosome 3 carries in one half the gene for pinkness and in the other that for whiteness, and since colour is in this case dominant, the hybrid bears pink flowers. Now let this hybrid be self-fertilised and it is easy to predict that of sixty-four seedlings there will be on the average one which exhibits *all* the recessive characters—that is, it will be a dwarf, perpetual-flowering, fully double white Rose with mixed characters of R. multiflora and R. chinensis; and this is indeed the origin of the Polyantha Pompon Rose Paquerette, raised by M. Guillot, in 1873, which introduced a new race to Roses to our gardens. It needs no further illustration to convince anyone that a thorough investigation of the chromosomes of species and varieties of Rosa, or of any other garden plant, is bound to throw yet more light on the origins of, and relations between these plants. These investigations Major Hurst has carried out with admirable skill and patience. He finds that in the genus Rosa there are six different types with fourteen (seven double), twenty-one, twenty-eight, thirty-five, forty-two and fifty-six chromosomes in the body cells. Wordsworth's little cottage maid should have been named Rosa, for she could truly say " we are seven." These chromosomes run in septets, that is, groups of seven, and throughout all the Roses there are no more than five septets—which may be called A, B, C, D, E. In the chromosomes of such septets a *different set* of genes is carried, and these genes represent collectively not less than one hundred specific, sub-specific or varietal characters. It may, therefore, be concluded that the genus Rosa of Linnaeus is composed of five fundamental species, and that all other species are derivative, that is, have been formed by combining and recombining the characters of two or more of these fundamentals. All these are diploids, that is, each of them contains two sets (*i.e.*, two septets) of seven chromosomes in their body cells. Other Rosa species are polyploid, that is, they contain more than two septets; they may be triploids with three septets, tetraploids with four, pentaploids with five, hexaploids with six and octoploids with eight septets of chromosomes in their body cells. The five fundamental species may be represented symbolically thus: Species 1, with AA septet of chromosomes; viz., R. sempervirens and all its sub-species and derivatives, among which figure the Tea Rose, Banksian China Rose, R. anemoneflora, R. cathayensis, and its offspring Crimson Rambler, R. multiflora, R. Wichuraiana, and so on. The characters distinguishing the AA septet species have been determined and enumerated by Major Hurst, who also diagnoses in like manner the other four fundamental species. Thus R. sericea and its group carries the BB septet and embraces R. Willmottiae, R. Hugonis, etc. No. 3 species—CC septet species—is R. rugosa, with sundry others less known, and also R. nitida. No. 4, DD septet species, is ranged around R. carolina, and the fifth, EE septet, is R. macrophylla. So much for a bare outline, sufficient perhaps to show how this new method is being applied to solve the age-long problem of the nature and origin of species. Those who appreciate the importance of the subject will not be deterred by the difficulties which it presents from studying the genetical method of species determination so brilliantly expounded by Major Hurst.

John Cypher Memorial Fund.—Since the publication of the previous list of contributions to the John Cypher Memorial Fund, the following amounts have been received and acknowledged:—Mr. Edgar Ingham, Saville Heath, Halifax, £1; Mr. E. T. Gilman, Rugeley, £1 1s.; Mr. W. R. Manning, Dudley, £2 2s.; Messrs. Blackmore and Langdon, Bath, £3; Mr. A. E. Usher, Blandford, 10s. 6d.; Shropshire Horticultural Society, £26 5s.; Mr. Peter Blair, Stoke-on-Trent, 10s. 6d.; Mr. Pritchard, Aldenham, 5s.; Mr. H. G. Alexander, Westonbirt, £2 2s.; Messrs. J. and A. McBean, Cooksbridge, £2 2s.; Alderman E. Wood, Southport, £1 1s.; Alderman W. H. Potts, Southport, £1 1s.; Alderman R. Sanderson, Southport, £1 1s.; Mr. J. T. Wilkinson, Southport, £1 1s.; Mr.

Transom, Southport, £1 1s.; and Mr. J. R. Billington, Southport, £1 1s. The Council of the Royal Horticultural Society has promised a donation of £10. Further donations will be gladly received and acknowledged by the Hon. Secretary and Treasurer, Mr. Charles H. Curtis, 5, Tavistock Street, Covent Garden, London, W.C.2.

The History of Plantation Rubber.—The *Daily Telegraph* published with its issue of November 19, an interesting supplement on the Rubber Industry, containing articles tracing the phenomenal growth in the use of rubber articles—the chief of which is the motor tyre—which has taken place in the last quarter-of-a-century. It is generally known that until thirty years ago the comparatively small amount of rubber which was used was largely from wild rubber trees, but with the development of the motor industry, special plantations have been established, mainly in the Dutch and British East Indies and in Ceylon—in the latter island, indeed, the acreage under rubber exceeds that of the Tea plantations. The story of the first importation of the seeds of Hevea brasiliensis from the forests of the Amazon by Henry A. Wickham, acting on the instructions of Sir Joseph Hooker (then Director of Kew), and of Sir Clements Markham, of the India Office, is too well-known to require more than a passing reference. The seeds were safely brought to Kew, and were distributed thence in 1876, being sent to Ceylon, Singapore, Perak, and later, to Malaya. But it was not until comparatively recent years that planting was undertaken to the extent, or in the careful and systematic way, that the modern demand for rubber has necessitated. In the earlier days of plantation, great trouble was experienced from the prevalence of malaria, but to-day, thanks largely to the genius of Sir Malcolm Watson, Malaya is wonderfully free from this scourge of the tropics. In the article entitled "Laying out a Modern Plantation," interesting details are given of the method of planting the young rubber trees on a specially prepared clearing from which the former jungle has been carefully burned away. It has been found that the maximum number of trees to the acre should be from one hundred to one-hundred-and-fifty, thinning being practised if more are planted in the first instance. As might be expected in a fertile soil, with tropical conditions, weeding is a hard and often hopeless task, and has been in many places superseded by the establishment of Leguminous ground plants to keep in check the more luxuriant jungle growths. Insect pests also abound, and fungus diseases take a heavy toll. Tapping is not commenced until after about five years of growth, the test as to whether a tree is ready being determined by the growth made. As a rule, it is safe to tap a tree which is eighteen inches in circumference at three feet from the ground.

Legacies to Gardeners.—Mrs. Margaret Lewin, of Parkhurst, Abinger Common, Dorking, who died on July 12, 1929, left £100 to Mr. Timothy Brewer, gardener.—Mr. George Thomas Hawkins, of The Rowans, Cliftonville, Northampton, who died on September 3, 1929, left £50 to his gardener, Mr. William Green.—Mr. Harry Coulby, of Ohio and the Ritz Hotel, London, who died on January 18, 1929, left to his gardener a legacy equal to the total amount of wages received while in his employ.

The R.H.S. Gardeners' Diary, 1930.—This handy diary is now available, and it is too well-known to require any further recommendation. It is published under the auspices of the Royal Horticultural Society in conjunction with the famous firm of diarists, Messrs. Charles Letts and Co., and may be obtained from the Royal Horticultural Society, from this office, or from any stationer, the price being 2s., bound in cloth cover, with pencil, or 5s. in refillable leather case, with pencil and pockets.

Honorary Fellowship of the R.H.S. for Clerk to the Gardeners' Company.—At the recent Livery Banquet of the Worshipful Company of Gardeners, Mr. Gerald W. E. Loder, the President of the Royal Horticultural Society, handed to Mr. E. A. Ebblewhite, the Clerk to the Company, a diploma conferring on him the Honorary Fellowship of the R.H.S. in recognition of his long services as Clerk. The Master of the Company, Mr. Edward N. Sherwood, of Messrs. Hurst and Son, presided over the Banquet.

M. Joseph Bol.—A well-to-do business gentleman and President of the Syndical Chambre of Manufacturers of Mechanical Music, M. Joseph Bol nevertheless devotes considerable time to horticulture and is an enthusiastic amateur. In 1927, he founded the Belgian Chrysanthemum Society, which held its first exhibition in 1928, and an admirable second one during the present year, as reported in *The Gardeners' Chronicle* of November 2, p. 354. M. J. Bol finds that a large measure of the happiness of life results from service to others, and so we find that he is treasurer of the Belgian Royal Federation of Horticultural Societies, and occupies a similar position in the Belgian Fleurie, which has for its aim the horticultural improvement of every town and village in his country during the coming year, when Belgium will celebrate the centenary of her independence. M. Bol's slogan is "Flowers and still more flowers, and gardens for everyone."

M. JOSEPH BOL.

Rock Garden Society.—The first General Meeting of the Rock Garden Society will be held in the new hall of the Royal Horticultural Society, on Tuesday, December 10, at 3 p.m. The business of the meeting will be to appoint the officers and set out the objects of the Society and to arrange the date for the Society's first show in 1930. All interested in the cultivation of alpine plants are invited to attend.

Horticultural College, Swanley.—The Annual General Meeting of the Horticultural College, Swanley, was held on Tuesday, November 19, at 29, Bryanston Court, W.1, at 4 p.m. Lady Falmouth, the Chairman, in moving the adoption of the Report and Accounts, referred to the recent developments at the College. A new dairy had been built and the College was now fully equipped to give instruction in modern methods of production of clean milk, and in the making of butter and cheese. A new herd was being built up of tuberculin-tested animals suitable for the production of Grade A milk. Lady Falmouth mentioned further developments which were now contemplated if sufficient funds could be obtained. The enlargement of the Staff House and the rebuilding of the range of conservatories were really urgent, she said. She also referred to the great need for more scholarships to meet the demand of students who were anxious to obtain a horticultural training, but could not do so without financial help. The meeting closed with a vote of thanks to the Chairman, proposed by Sir William Lobjoit and seconded by Miss Cohen.

Retirement of Mr. W. Warnaar.—One of the best-known personalities in the horticultural world of Holland is Mr. W. Warnaar, the head of the bulb-growing firm of that name which has such extensive fields just outside Haarlem. He has interested himself in horticulture, and done his utmost to secure its progress in his country, in every possible way, and is deservedly famous far beyond the confines of Holland. He has, however, lately come to the conclusion that it is time to retire from some of his many activities and take more rest than he has hitherto been able to do, and this decision was celebrated on November 4 by a large gathering of his friends at the Krelage Building in Haarlem. Thirteen horticultural societies were represented, and Mr. Warnaar was received, with his family, by Mr. E. H. Krelage, who spoke warmly of the excellent results which had been brought about by his guest's work and enterprise, and presented him, on behalf of those present, with a writing table and chair. Other speeches followed, and Mr. Warnaar then replied, expressing deep gratitude and appreciation for these marks of the esteem in which he is held. His decision is doubtless a wise one, but it will be long before his place can be adequately filled. We should like to join with his other friends in wishing him many long and pleasant years in which to enjoy his well-earned rest.

Habenaria Lugardii.—Major E. J. Lugard writes: "On page 333 of your issue of October 26, in reporting on the R.H.S. Fourth Autumn Show, you refer to Habenaria Lugardii as an 'extremely interesting and distinct Orchid collected in the Congo region.' Habenaria Lugardii (Fig. 156, page 338) was discovered by me in the Botletle Valley, Ngamiland, South-central Africa, in 1898, and was presented by me to the Royal Gardens, Kew, in February, 1899. It is fully described in the *Flora of Tropical Africa*, Vol. VII, p. 228, and is beautifully illustrated in the *Botanical Magazine* of October 1, 1901. It was previously referred to in *The Gardeners' Chronicle* in 1900, Vol. II, p. 322. It would be interesting to know if it has since been discovered in the Congo."

Fastigiate and Pyramidal Trees.—Some interesting observations and supplementary remarks by the Hon. Vicary Gibbs on Mr. W. J. Bean's article on "Fastigiate and Pyramidal Trees," which appeared in the Kew *Bulletin of Miscellaneous Information*, No. 4, 1929, and was subsequently reproduced in *The Gardeners' Chronicle*, appear in the current issue of the Kew *Bulletin*. The author confirms Mr. Bean's statement that nearly every common tree has a fastigiate form, but, whereas Mr. Bean's exceptions included the Ash, the Lime and the Sycamore, the last-named is the only one of which the Hon. Vicary Gibbs has not discovered a fastigiate form. He found a fastigiate form of the Ash in Mr. Trotter's grounds at Leith Vale a year or two ago, and has this year succeeded with a few grafts of it; he states that the boughs of this Ash turn up vertically, but it is not narrowly fastigiate and is therefore not so effective as the Hornbeam of similar aberrant form. At Aldenham there is a fastigiate Lime—Tilia platyphyllos var. pyramidalis—which is now a shapely pyramid about twenty feet high and doing well. The unique Elm mentioned by Mr. Bean as growing at Aldenham, was blown down about a year ago, but some of its growths were preserved and grafted successfully. Mr. Gibbs states that Bolles' White Poplar, praised by Mr. Bean, is a dismal failure in the heavy soil at Aldenham: its branches keep dying back, and in self-consolation it produces suckers over a wide area, with the result that it is not regarded with favour. Alnus glutinosa var. pyramidalis, omitted by Mr. Bean, is included in the Aldenham collection, and stated to be well worth growing, being of very neat and compact habit; an excellent illustration of this fastigiate Alder accompanies the Hon. Vicary Gibbs' notes. He has two plants of the pyramidal Spanish Chestnut, originally suckers from the original tree at Mount Mascal, and besides the two forms of Robinia Pseudacacia mentioned by Mr. Bean, there is at Aldenham a third—R. p. var. inermis fastigiata—a quite distinct and striking form. The upright-growing form of Ulmus montana is decidedly decorative when its growths are trimmed in fairly closely, while another Elm at Aldenham, U. nitens var. umbraculifera gracilis, although not strictly a pyramidal tree, forms a neat bush of thin growths, with no central stem and all nearly vertical, in appearance like a mason's mallet, about fourteen feet high and twelve feet through. In form it is somewhat like Carpinus Betulus var. pyramidalis. There is also at Aldenham an exceedingly narrow form of the Irish Yew, called var. columnaris. Other plants omitted from Mr. Bean's account include a very narrowly upright form of the Scots Pine, growing at Glasnevin, and of which the Hon. Vicary Gibbs has a grafted plant now about eight feet high; two very narrow forms of Juniperus chinensis—the green one, and that known as Young's Golden Juniper; and a narrowly-upright form of Cedrus atlantica. Pseudotsuga Douglasii var. pyramidalis, now ten feet high at Aldenham, is another addition to the list of fastigiate Conifers. Mr. Gibbs suggests that Betula pumila var. fastigiata should be included, and also considers that Amelanchier florida is certainly either fastigiate or pyramidal. He states that some of the cultivated Pears, such as the variety Charles Ernest, are undoubtedly fastigiate in form; also the Crab Apple, Pyrus Malus var. magdeburgensis. He concludes his notes with mention of two fastigiate forms which, although not attaining the dignity of trees, are worthy of mention. The first of these is Sambucus nigra var. fastigiata, suggested as a useful subject for planting in small gardens to block out unsightly buildings, etc., as it makes a very solid column and is rapid in growth. The second plant is the narrow form of Aralia chinensis, which has the advantage of taking up less room than the type, but has the disadvantage of suckering too freely. In his acknowledgment to Mr. Vicary Gibbs, Dr. Hill mentions a fastigiate form of Populus tremula, which was pointed out to him by Professor R. E. Fries during a visit to the Hortus Bergianus, Stockholm, in July.

Preservation of Wood.—At the invitation of Sir Harold Boulton and Sir James Calder, a meeting is to be held at 3 p.m. on December 3, at the Hotel Metropole, Northumberland Avenue, W.C.2, to discuss the formation of a Wood Preserving Association. The Association has as its chief object the prevention of wastage of wood caused by neglect to use proper means of preservation against rot and the attacks of insects. Although it has been customary for many years in the United Kingdom to use protectively treated wood for railway sleepers, telegraph poles, piles and fencing posts, those who are interested in the formation of the association feel that this practice should be extended to wood used for many other purposes, such as fences, all manner of buildings, wooden structures, wagons, etc., not only in the United Kingdom, but throughout the world, in order to preserve timber resources, especially those of the British Empire. It is proposed that the Association should examine the cause of destruction or deterioration of wood and investigate all the processes or methods used or suggested for its protection. In the United Kingdom the activities of the Association will be particularly directed towards the prevention of waste of home-grown timber in order that home forestry may be assisted. The Association hopes to co-ordinate practical and commercial research in all parts, in which task it will receive the co-operation of His Majesty's Forest Products Research Laboratory at Princes Risborough. It will also give close attention to the matter of specifications for wood preservatives and adherence thereto. Lord Clinton, accompanied by other Forestry Commissioners, will attend the meeting. His Majesty's Post Office and the four Railway Groups will be represented. Representatives will also attend from the principal timber preserving interests in the country, from many timber firms, from the Timber Trade Federation, from many estate owners, and from among those interested in forestry or in the manufacture of timber preserving preparations. It is hoped that anyone interested in wood preservation who may not have hitherto received notification of the scheme to form a Wood Preserving Association will at once apply to Sir Harold Boulton, 166, Piccadilly, W.1, for an invitation to the meeting on December 3.

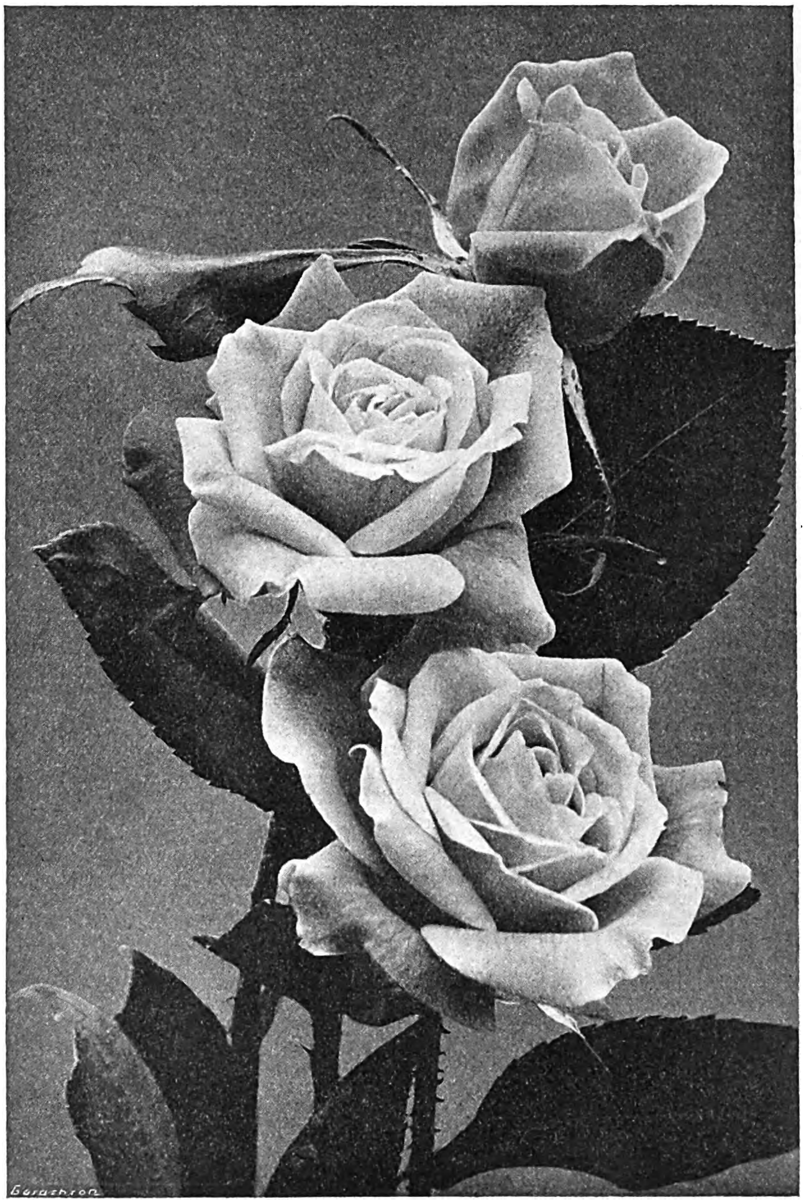

FIG. 193.—ROSE AUTUMN.

R.H.S. Award of Merit, November 19. Flowers yellow and rose. Shown by Mr. C. Engelmann.
(see p. 412.)

Appointments for the Ensuing Week.—MONDAY, DECEMBER 2: Derbyshire Horticultural Association's meeting; National Chrysanthemum Society's Floral Committee meets. TUESDAY, DECEMBER 3: Royal Caledonian Horticultural Society's meeting. WEDNESDAY, DECEMBER 4: National Carnation and Picotee Society's meeting; Wimbledon Gardeners' Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment Holders' Association's meeting. THURSDAY, DECEMBER 5: Bideford and District Horticultural Society's meeting; Portsmouth Horticultural Society's lecture. FRIDAY, DECEMBER 6: Dundee Horticultural Society's lecture. SATURDAY, DECEMBER 7: Leeds Paxton Society's Open Exhibition Night.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Frigi Domo.*—After two winters' experience of this material as a protection from frost, I have come to the conclusion that it is the best covering for pits and frames which ever came under my notice. It will keep out more frost than two mats, while it only costs the price of one; it is more tidy than loose litter, and fits more closely than straw hurdles, and it is much more manageable, for when fitted on to a roller end-ways, covering and uncovering can be effected in half the usual time, and there is no danger of breaking the glass. In wet weather it lies quite close to the glass, but so soon as frost sets in it becomes almost as tight as a drum, thus forming a space between it and the glass, a thing very desirable where the edges fit tightly, which they do. I believe that any greenhouse plant is perfectly safe under it until the thermometer indicates 10° of frost. *J. Rust, Broom House, Fulham. Gard. Chron., December 2, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Duckyls Park, East Grinstead, Sussex.

The Cattleya House.—The autumn-flowering kinds of the large group of plants accommodated in this house, make a gorgeous display of colour at this season; the varieties are too numerous to enumerate, or treat separately, many new and good sorts being introduced every year. As the plants pass out of flower the old flower spikes and sheaths should be removed by severing both so closely as possible to the pseudo-bulb without injuring it; if left on the plant, these will often collect moisture which may set up decay in the leaf and psuedo-bulb. It is advisable to sprinkle a little powdered charcoal on the cut surface to prevent decay. At this stage the plants should be placed in a light and well-ventilated position, and kept slightly drier at the roots than when bearing flowers, sufficient moisture only being given to keep the roots healthy and the pseudo-bulbs in a plump condition. The compost should be allowed to dry well between each application of water. This partial rest should enable the plants to recuperate, and they should grow vigorously in their proper season. As the plants of the late winter and spring-flowering varieties complete their growths, water should be afforded sparingly, only sufficient being required to keep the roots fresh and the pseudo-bulbs plump. When the flower buds are seen growing up in the sheaths, an increased supply will be needed to assist in their full development. Plants that are making secondary growths should be given a light and warm position to assist in building up the pseudo-bulbs so soon as possible.

Lycastes. — Various members of this well-known genus, notably L. Skinneri and its varieties, and the hybrids of L. Balliae and L. Lucianii and others, are now completing their season's growth and flower buds should soon be showing at the bases of the new pseudo-bulbs. Lycastes require plenty of water at the roots during the growing season each time the compost becomes dry. At this season somewhat drier conditions should be maintained, although the plants should not be allowed to shrivel through lack of moisture. Under these partial-resting conditions a larger quantity of blooms may develop at one time. When flowering has finished only sufficient water is required at fairly long intervals to keep the plants in a plump condition. These Lycastes grow well in the cool house during the summer months, but it is advisable to remove them to slightly warmer and drier conditions, with plenty of light, at this season. Similar cultural treatment should be afforded the fragrant L. aromatica, also L. candida var. Lawrenceana and L. Deppei, while the white-flowered, night-scented L. lanipes, together with the free-flowering L. Barringtoniae, and the distinct, L. leucantha, require an intermediate temperature all the year round. The large, mealy scale which often attacks Lycastes on the undersides of the leaves should be removed by careful sponging with soapy water when detected. The flowers of Lycastes last for many weeks, and weak plants should have their flowers removed at an early stage, or they may become exhausted.

Mexican Laelias.— Members of this group of graceful-flowered Laelias, notably L. anceps and its numerous varieties, together with L. Gouldiana, are now developing flower buds at the tops of the long, slender stems, while the blooms of the fragrant Laelia autumnalis are now fully expanded, and these should last a long time if kept in a fairly dry atmosphere. The gummy substance exuded around the buds of plants of this group of Laelias should be carefully removed by gently passing a wet sponge over the buds in an upward direction; if allowed to remain it often prevents the blooms expanding. When in bloom the plants should be afforded drier atmospheric conditions than was required during the growing season, and they should also receive so much light as possible, in a position where the long spikes will be free from contact with the roof-glass, otherwise the blooms may be seriously damaged. Sufficient water should be given to the roots to allow the flowers to develop, and after the flowers have been removed, the development of the pseudo-bulbs being already completed, very little water at fairly long intervals should suffice to keep the pseudo-bulbs plump, but in a dormant state, until the early spring months; at which season new roots should be produced from the base of the new pseudo-bulbs and any necessary repotting may be done safely. Water should be given very sparingly until the new roots have obtained a good hold of the new compost of fibre and moss. Plenty of fresh air should be admitted to these Orchids on all favourable occasions. The white varieties of L. anceps are mostly robust growers, but unless the growths are well ripened they fail to produce flower spikes. The past summer has been favourable to the development of these Laelias, as they revel in sun-heat. These white-flowered forms are usually a few weeks later in flowering than the coloured forms, and should be seen at their best early in the New Year. Scale insects increase rapidly under the drier conditions, and these should be removed by sponging so soon as detected.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Apple and Pear Trees in Borders.—Bush or pyramid Apple and Pear trees growing in the borders of the kitchen garden should be pruned early, in order that the necessary preparation of the soil for spring cropping may be carried out. Trees which have carried heavy crops of fruits this season, and those which are making poor and stunted growth, should have the surface soil removed to a depth of several inches and to the outward spread of the branches. A dressing of bone-meal, two handfuls to the square yard, and half that quantity of sulphate of potash should then be pricked lightly into the soil among the roots, and a top-dressing given of a mixture of equal parts of good, turfy loam and well-rotted farmyard manure, the whole being made very firm by treading. Pears are more commonly grown as pyramids than as bushes, owing to the natural habit of the trees favouring that form; the pruning of these at this season corresponds generally with that practised for Apple trees, but the pruning should cease gradually from about the eighth year, when the framework of the tree has been formed. Thereafter, little or no pruning will be needed, beyond the removal of water-shoots, or an occasional thinning of the branches as the tree advances in age. Young standard trees that were planted last season should have their stakes and ties examined and made good, and where there is a risk of hares or rabbits gaining access to the garden during severe weather, the stems of all young fruit trees should be protected with wire-netting.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Chrysanthemums.—As these pass out of flower the plants required for stock purposes should be selected, and stood in a light position either in frames or in a cool fruit house where plenty of light and air is available. Under these conditions a supply of strong, sturdy cuttings should be forthcoming; guard against attacks of mildew and aphis. Some varieties are very shy in producing cuttings, and these should be shaken out, potted in fresh compost and placed in a warm house.

Propagating Chrysanthemums.—Certain varieties of Chrysanthemums that are grown to produce large exhibition flowers demand a long season of growth. These include such popular sorts as W. Rigby, Mrs. G. Drabble, Majestic and its sports, Victory, Queen Mary, Princess Mary, Mrs. J. Gibson and Miss Ada Ellis; and with these early propagation is essential. The cuttings may be inserted singly in small sixty-sized pots, or three may be inserted in larger receptacles. Where space is limited the latter method may prove more convenient and provided the young plants are potted on singly so soon as roots are well-formed, plants equally as good as those rooted singly should be obtained. The receptacles should be filled with light, open soil which should not be made too firm, and when the cuttings are inserted water should be given immediately to prevent the cuttings flagging. It is a great mistake to attempt to root Chrysanthemum cuttings in strong heat, for this will probably only end in failure. A temperature of about 50° is desirable. The cuttings should be placed in a propagating case, and the lights removed for a short time each morning to allow the condensed moisture to evaporate. When the cuttings are rooted they should be gradually inured to the light, being placed near the roof-glass.

Lilium longiflorum.—Newly imported bulbs of this Lily, commonly known as L. Harrisii, should be potted so soon as they arrive, for it is not advisable to allow the bulbs to remain out of the soil for any length of time after their arrival. A light, open compost is best for most Lilies, and after being potted they should be placed in a frame from which frost can be excluded, until root action takes place. By introducing these Lilies into heat at intervals they may be had in flower over a considerable period, but much will depend on the treatment meted out to them. If grown under cool conditions, care should be taken when applying moisture to the roots. Liliums that have been grown in pots for a season, such as L. auratum, L. speciosum var. album and L. s. var. rubrum, and others, should, if desired, be repotted. When potting stem-rooting Lilies, leave sufficient space in the pots for top-dressings during the growing season.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Late Vineries.—Late houses in which ripe Grapes are hanging cannot be kept too cool and airy during mild, dry weather; a temperature of 50° is safe for all black Grapes, but Muscats may have a little more heat. The fall of the leaf is a trying time, especially in low structures; damp may be counteracted by collecting the leaves, covering the borders, warming the pipes, opening the ventilators on fine days, and keeping the house closed when the external atmosphere is heavily charged with moisture. Houses in which only a few bunches of Grapes are hanging may now be cleared with advantage to the fruit and vines. When cutting Grapes before the leaves fall, the latter should be left on to ripen and drop.

Cucumbers.—If fermenting leaves are used for producing or supplementing the bottom-heat, the syringe will hardly be needed. Plants in bearing may receive doses of weak, warm liquid manure at a temperature of 80° to 85°, but unless later plants are weak, pure water should maintain healthy growth of medium vigour on these, which should then not be affected by bad weather. Important points in the management of Cucumbers at this season are—cleanliness, and the husbanding of the strength of the plants by the removal of all young shoots not likely to be required, especially where the demand for fruits will be greater from the beginning of January onwards. Present supplies should be obtained from old or early autumn plants, which should be discarded when the real winter plants come into bearing from January to March. This may be accomplished by going carefully over the plants once or twice a week; by judicious stopping and thin training of the growths; by maintaining a moist bottom-heat of 75° to 80°; avoiding dry fire-heat and allowing the night temperature to range so low as 65° after nightfall. Insect pests nearly always find their way into Cucumber houses, especially if the plants are weak and unhealthy, and the best means of guarding against this is to insure cleanliness and avoid any attempt at crowding the plants. A circulation of fresh, warm air should be maintained whenever possible. If the plants are kept healthy and the fruits are grown quickly and cut when young, the bitter taste so frequently complained of in winter Cucumbers should be entirely absent.

Pot Cherries.—If the earliest trees have not been housed, no time should be lost in getting them cleansed and protected from severe frosts. If the weather is moist and mild, all the ventilators of the house may be left open night and day until the buds show signs of swelling. The roots, too, will require plenty of water, especially if pot-bound, as all stone fruits should be for early forcing. Trees planted out in inside borders require similar attention as regards a supply of fresh air. A good soaking with water at a temperature of 70° when the trees are started and the buds are on the move, is a great help. Plum trees for early fruiting require similar treatment to that advised for Cherries. Very old trees which seldom make any strong growths should never feel the lack of water, and this applies also to trees growing in narrow borders against the back wall of a lean-to house. If Cherries or Plums prepared in the open borders are well set with buds, they may still be lifted and potted, but they should not be forced.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Cold Frames.—Those containing cuttings of bedding plants now require careful attention. Frosts may be expected at any time, therefore protecting material should be in readiness for covering them when required. During the short, dull days of winter it is essential that these half-hardy plants should have a free circulation of air on every favourable occasion. Dampness and decaying leaves are much more destructive than cold, therefore all frames should be examined at least once a week, the decayed leaves removed, and the soil gently stirred on the surface. By doing this, and admitting ample air during mild weather, the loss of plants during winter may be minimised.

Pleasure Grounds.—At this time of year it is difficult to keep pleasure grounds tidy, if the presence of falling leaves can be called untidiness. It is certainly necessary to remove these from gravel paths that are in constant use, otherwise they make walking unpleasant during wet weather, and also ruin good paths if allowed to lie and decay on them. Where the leaves have gathered to any depth on lawns they should be collected or they may destroy the grass, but the general cleaning up may, with advantage, be left for a few weeks yet.

Berried Shrubs and Trees.—If there is any truth in the old saying that a hard winter follows a profusion of berries, we are likely to have some severe weather before us, as a large number of the berry-bearing trees and shrubs are freely fruited this year. In the case of the Holly and Hawthorn it is remarkable, the trees being laden with fruits, but the profusion of berries is not confined to these alone; the different species and varieties of Pyrus, Berberis, Rosa, including the common Briar, are bearing exceptionally heavy crops this year. Although December is not looked upon generally as a good month for planting, any of these deciduous trees or shrubs may be planted during open weather when the ground is in a dry, friable condition.

Subjects for covering Banks, Old Trees, etc.—Steep banks, old dilapidated trees, etc., may be made beautiful by being planted with flowering subjects. Among rambling plants for such a purpose are Clematis montana, C. m. var. rubens, C. Flammula, C. tangutica and many of the strong-growing climbing Roses. For a moist, shady spot, Tropaeolum speciosum is a desirable climber, as when once established it grows vigorously, making a brilliant display all the summer with its bright scarlet flowers. On some soils this plant is difficult to establish, and it is advisable to prepare the sites by removing at least a foot of soil and filling up with a compost of gritty soil; shade and coolness at the roots are essential conditions to its success.

Wall Plants.—In a few instances plants on walls were badly damaged last winter and if any gaps still exist now is the time to fill them. Free-flowering plants rather than those of an evergreen nature, should be chosen for this purpose. Before replanting make sure the soil in the border is in good condition, as but little renovating can be done after the plants become established, especially if the borders are narrow. A few subjects that should give satisfaction and require very little attention are Abutilon megapotamicum, Lippia (Aloysia) citriodora, Berberidopsis corallina, Ceanothus divaricatus, C. rigidus and C. Veitchii, these three evergreen Ceanothuses being very suitable for walls facing south or west; Escallonia exoniensis, and E. rubra; Passiflora coerulea, which produces an abundance of drooping mauve flowers, and its white form, P. Constance Elliott; Solanum crispum, a quick-growing plant producing an abundance of bright blue flowers if grown in a warm, sheltered corner; Tecoma radicans, Chimonanthus fragrans and Cestrum (Habrothamnus) elegans.

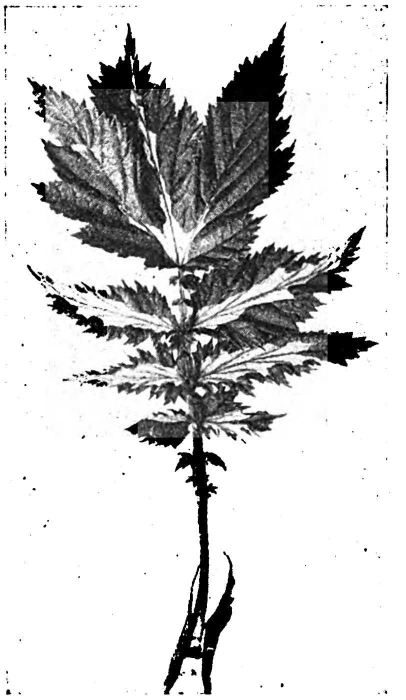

FIG. 194.—SPIRAEA ULMARIA VAR. AUREA.

(see p. 424.)

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Forcing Rhubarb, Seakale, etc.—A few clumps of Rhubarb, also crowns of Seakale and Chicory, may now be introduced into the forcing house. A brisk bottom-heat should be maintained to encourage quick growth, and a steady house temperature of about 60° should be found most conducive to good development. Endive plants may be placed in boxes in the forcing house to bleach them. They should be watered with care, as Endive is very liable to damp off quickly in a warm temperature if afforded an excessive amount of moisture.

Frames.—Carrots, Lettuces, Endive, Cauliflowers, etc., growing in frames should be inspected carefully on a dry day, and have all dead leaves removed. The surface of the soil about the plants should be stirred with a small hoe, and the frames should be ventilated with care. Any loose or broken panes of glass in the lights should receive attention, as the drip of water from these during wet weather is liable to prove very injurious to the plants growing beneath them, causing them to damp off and decay.

Tomatos.—Late Tomato plants growing in pots which were moved under glass a few weeks ago, are now carrying good and valuable crops of fruits. The leaves may be shortened, and if any side growths appear they should be pinched off; the terminal growth should also be stopped if this has not already been attended to. A dry atmosphere and a temperature of between 55° and 60° should be maintained, and careful watering practised. Liquid manure, in the form of a solution of Clay's fertiliser, should be given at intervals of about ten days to assist the swelling and colouring of the fruits.

Cucumbers.—Late Cucumber plants which are now coming into bearing need very careful attention to watering and thinning out the surplus growths. See that the plants obtain so much light as possible, and so regulate the growth that there is no overcrowding. A steady temperature should be maintained.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Lawns.—In most cases lawns are greatly improved by an annual dressing of sand, and on heavy land this is almost essential if a good firm surface is to be maintained. Good sharp gritty sand is best, and if applied now it becomes so well embedded in the surface that no trouble is experienced in cutting the following year. If lawns are very soft and hold the water, draining should be carried out, or the existing drains attended to. Shallow drains eighteen inches below the surface, and not more than twelve feet apart, should prove satisfactory in bad cases, while they may be slightly deeper and wider apart where better soil conditions obtain. If the surface of the lawn has become too solid, it should be pierced all over with an instrument made for the purpose. Any weeds, such as Daisies, Plantains, or other broad-leaved weeds, should be removed with a "spud," and moss cleaned off with a close-toothed rake. Manure for lawns are more economically applied in spring, just before growth commences.

Fan-Trained Apples and Pears.—As these differ somewhat from Plums and Cherries, which were dealt with last week, a few notes on their pruning may not be out of place. The extension system of training is applicable to both, but not so necessary as with stone fruits. The leading shoots may, in many cases, be found to have one or more fruit buds at the top, so that they should be cut back to a wood bud if further extension is necessary. Provided the spurs are kept short by periodical removal as they elongate, it is possible to retain the same branches in good fruiting condition for many years, which, of course, is important.

Ground for Potatos.—When quality, combined with a reasonable crop of Potatos, is wanted, as apart from mere bulk, some consideration is necessary in preparing ground that is heavy and cold. A plot of medium loamy soil which has been well enriched with farmyard manure for the previous crop should be chosen, if possible, and should be well exposed to the sun for the greater part of the day. This should be trenched or double-dug, according to its depth and the quality of the subsoil, so early as possible. Leave the surface rough or laid up in ridges as desired. Manure should only be added to the soil if poor, and then only light, partly decomposed manure should be employed, working it well in as the work proceeds.

Lily-of-the-Valley.—A few boxes should be filled with turves cut where the crowns are thickest in the bed, and kept in readiness for forcing as required. Another method is to select the three-year-old crowns and pot them, re-planting the younger crowns in well manured and deeply-dug cultivated ground, in a partially shaded corner not too much in evidence during summer.

TREES AND SHRUBS.

JUGLANS CINEREA.

I have, this autumn, greatly admired the brilliant colouring displayed by the Butternut, Juglans cinerea. The display was, admittedly, not long-lived, but of the most beautiful shades of orange-scarlet, so that a specimen or two in a hillside wood were strikingly lovely.

The insignificant greenish flowers of this species are succeeded by rather small, oblong-ovate nuts, tapering to a point, slightly downy and covered with small, transparent glands of viscid matter; they are pendulous, on flexible peduncles.

J. cinerea has for long been known in gardens, as it was introduced from North America in 1656, and is figured in *Bot. Mag.*, t. 247.

Some large examples of Crataegus Crus-gallii var. ovalifolia close to the Butternut, maintain some fine colouring for a considerable period, and the background to this effective planting is well provided by Norway Maples. *Ralph E. Arnold.*

PACHYSTIMA CANBYI.

Those who like uncommon shrubs, especially dwarfs which enjoy peaty soils and woodland conditions, will find this an interesting subject. A native of Virginia and north Carolina where, however, its range is curiously limited, Pachystima Canbyi is a lowly, compact evergreen, normally under one foot high, with an inclination to a semi-procumbent habit. The small, narrowly oblong leaves, which have decurved margins, are usually less than an inch in length and of a rich glossy green. The leaf axils become tufted with small, greenish blossoms in summer, but neither these nor the fruits, which I have never seen, are of any ornamental value. This is a shrub, as I have stated, for those who appreciate out-of-the-way things, and who have the right conditions.

I have grown P. Canbyi for a good many years among Gaultherias, Ledums and other plants of the kind. Its green is always cheerful, it takes care of itself, and makes a pleasant, non-interfering companion for its associates. I have never known this little shrub to be affected by frost. The finest specimen I have ever seen was in the late E. C. Buxton's garden, at Bettws-y-Coed. It was growing in a peaty crevice between slaty rocks and was about eighteen inches high and at one time two feet across. It was, I believe, at least twenty years old. *A. T. J.*

LEDUM LATIFOLIUM.

In our gardens, the small genus Ledum is generally represented by but two species, namely Ledum latifolium, the Labrador Tea, and L. palustre, the Marsh Ledum, both extremely hardy evergreen shrubs of low stature from the far north.

Of the two, L. latifolium is by far the most attractive and should be given preference where a choice has to be made, for it forms a compact bush of good form, is a handsome evergreen and is also effective when in bloom from late April to early June. It delights in peaty soil and partial shade, and may be associated with Azaleas, Kalmias, Vacciniums and other peat-loving subjects in the wild garden.

L. latifolium grows to about two-and-a-half feet high, and as much or more across, the bush being compact and rounded, and usually flattened at the top. The leaves are dark green and covered with rust-brown felt beneath, half-an-inch to two inches in length, and from a quarter- to half-an-inch in width, narrowly oblong or oval in shape, and with recurved margins.

The leaves of L. latifolium are stated to possess various medicinal properties. A decoction made from them is stated to be useful in the treatment of coughs, colds, bronchial and pulmonary troubles, and it is also recommended for external applications in the treatment of various skin troubles. The leaves, when bruised, emit an aromatic odour.

L. latifolium produces its blooms abundantly and regularly, in terminal, rounded clusters two inches or more in diameter, each flower being nearly half-an-inch across, creamy-white in colour, with protruding stamens which impart to the flowers a star-like effect.

It is common throughout northern America, including Greenland—hence its synonym, L. groenlandicum—and was introduced to cultivation in 1763. It is not uncommon in gardens, and may be increased by seeds, treated in the same way as are other small-seeded, Ericaceous shrubs; by cuttings, or by layering. There is a named variety of it, L. l. var. compactum, which has very woolly stems, smaller flower clusters, and short, broad leaves, and it is of dwarfer habit.

The Marsh Ledum, L. palustre, is a dwarf evergreen of thin and spreading habit, with narrow, linear leaves and clusters of flowers similar to those of L. latifolium, but with more stamens; it is found in the cold regions of North America, Europe and Asia, but is not a native of Britain. There are two varieties of note, var. dilatatum, with broader leaves, and var. hypoleucum, with white, woolly covering on the underside of the foliage.

The very desirable Sand Myrtle, Leiophyllum buxifolium, a low-growing evergreen shrub, with attractive pinkish flowers, red in the bud, was at one time commonly grown under the name of Ledum thymifolia, and was even figured in the *Botanical Magazine*, t. 6,752, under this name. It is closely related to Ledum, but is considered sufficiently distinct to merit generic rank. It is a grand subject for associating with Heaths. *M. W.*

HARDY FLOWER BORDER.

LYSIMACHIA CLETHROIDES.

The genus Lysimachia shows considerable variation in the characters of its members, some of which are dwarf and creeping in habit, as for instance, that old cottage garden favourite, the Creeping Jenny, L. Nummularia, while others are erect growing, herbaceous perennials. The majority of them have yellow flowers, but some have white blooms, and among these the handsomest is L. clethroides, in fact, this is probably the most strikingly decorative member of the genus. For not only is it very attractive, in habit and blossom, but in autumn its dying foliage often becomes richly tinted, thereby adding greatly to its decorativeness.

L. clethroides is an effective subject for the herbaceous border or, like some of the erect-growing, yellow-flowered species, it may be employed for furnishing the margins of ponds or streams, in bold groups, for it delights in a moist root-run and well-cultivated and enriched soil.

A native of Japan, it is perfectly hardy in this country and a free-growing, herbaceous perennial, spreading freely by means of underground growths, so that it should be so placed as to not endanger or encroach upon less vigorous and possibly more choice subjects; it is best lifted and replanted every third or fourth year, as unless attended to in this respect it deteriorates and becomes stunted, thereby losing much of its charm and gracefulness.

Its average height is between two and two-and-a-half feet, although sometimes it exceeds this. Of bushy, compact habit, it produces from July until late September, or even on into October, long, dense spikes of pure white blossoms, the upper portions of the spikes being bent over and curled downwards. This white-flowered Loosestrife does not object to partial shade and is, therefore, especially useful for such positions. It is a first-class herbaceous plant for late summer and autumn effect.

ACONITUM WILSONII.

There are now quite a large number of species of Aconitum, and forms of Aconitum Napellus, the common Monkshood, cultivated in gardens, but perhaps the handsomest of them all is A. Wilsonii, a comparative newcomer from China, yet already popular in many gardens.

It is a free-growing plant, forming a mass of dark foliage from among which arise the stout flower stems to a height of five feet or so, forming loose spikes, graceful in spite of their magnitude, of large, deep violet flowers carried on slender stems, the whole forming a grand and imposing column of bloom during late summer and early autumn.

A. Wilsonii is a very effective subject for the large herbaceous border, or it may be employed to great advantage by the waterside, where it may be planted in bold groups and left undisturbed for a number of years. It does not object to light shade and is, therefore, suitable for planting in open woodland.

Wherever A. Wilsonii is planted, the ground for it should be well prepared if it is to give of its best, for it is a gross feeder and delights in deeply worked, moderately moist and well enriched soil. It usually sets seeds freely, and from these fresh plants may be raised, or increase by division may be practised. *Kent.*

ALPINE GARDEN.

LINARIA ALPINA.

In his justly eulogistic article on Linaria alpina, *L. B. C.* (November 9) refers to the unprocurable albino of this plant, but does not mention two noteworthy varieties which are in cultivation, namely, concolor and rosea, unless, indeed, his remarks on forms of "dull bluish or pinky-whiteness" be taken to indicate the latter. These two resemble the type in all but colour. Linaria alpina var. rosea, as its name partially implies, has flowers of a colour usually described as "shrimp-pink," although paler, with a touch of bright orange on the lip; the concolor variety is purple, like L. alpina, but lacks its attractive "egg-yellow lip." They need no more care than the species of which they are varieties.

Linaria alpina flowers and seeds with the exuberance of an annual, and may conveniently be treated as one on the rock garden, for there is much of the annual in its nature. Old plants cannot be trusted to survive the winter, but this is a matter of little importance, as the seedlings which crop up the ensuing spring grow quickly into clumps of narrow, bluish foliage, and flower the same year. Plants may be bought and put in during spring, but seeds sprinkled over the rock garden in autumn should yield equally good results, provided the soil is well-drained and the place sunny. If something of a weed when established, owing to the cheerful way in which it seeds itself about, Linaria alpina has, at any rate, none of the troublesome underground spreading habits of L. pallida, and is a plant which the rock garden can ill do without. *W. T. S., Cambridge.*

HABERLEAS.

Whereas the Ramondias enjoy widespread popularity among alpine plant enthusiasts, their close relatives, the Haberleas, do not appear so popular, although where Ramondias will grow, there also will the Haberleas flourish. For these beautiful plants delight in cool, shady places, in the crevices of rocks with northern exposures, and with a moist, cool root-run in peaty loam.

Haberlea rhodopensis, native of the Balkan mountains, is the type plant of the genus and is, perhaps, most frequently grown in rock gardens. It forms close, Ramondia-like rosettes of rusty-haired, dark green and toothed foliage, and every rosette produces during May and June from one to five slender-stalked sprays of several blooms, like miniature Gloxinias, lilac-lavender in colour, with a gold-speckled, lighter throat.

H. rhodopensis has given rise to several good forms, for it varies considerably from seeds, and among the coloured varieties the most striking is that known as Ferdinandi-Coburgi, the flowers of which are larger and more richly-coloured than those of the type, and are produced with greater freedom. This Haberlea is sometimes classed as a distinct species.

One of the most chaste and beautiful of all alpine plants is the albino form of H. rhodopensis, known under the varietal name of virginalis, still rare in gardens and, withal, fairly expensive to purchase. It is so beautiful that unless possessed of a good stock one is not disposed to commit it to the open garden, preferring to afford it the shelter of the alpine house, for its pure white blooms are of delicate and refined loveliness.

The Haberleas may be raised from seeds, which are very minute and, consequently, require handling with care, or, like the Ramondias, they may be increased by leaf cuttings, fully developed leaves being selected for this purpose and their stalks inserted in sand in a warm propagating case. Young plantlets are formed from the buds at the bases of the leaves and these may be potted on, carefully hardened off, and grown on in a cold frame until large enough for planting out.

The Haberleas—especially the varieties Ferdinandi-Coburgi and virginalis—are very attractive claimants for cultivating in pans in the alpine house, to which treatment they respond well and are very striking when in bloom. They should be planted in a mixture of peat and loam, with a little silver sand, and with a layer of Sphagnum-moss above the crocks, and should have small pieces of rock wedged firmly about them; under alpine house treatment they should, of course, never be allowed to suffer from lack of moisture at the roots.

HUTCHINSIA ALPINA.

Hutchinsia alpina is one of those unpretentious alpine plants which, by reason of their cheerful disregard of changing seasons and variable weather, rank among the indispensable.

The spring is its flowering season, but it continues to produce its bright little clusters of flowers intermittently throughout the summer and autumn, and even now its verdant carpet is still dotted with bloom.

A native of the alpine regions of central and southern Europe, H. alpina is very easy to grow, delighting as it does in a cool rock crevice or a position at the base of a large rock or stepping stone, there to form a close mat of delicate, feathery foliage of refreshing greenness; it does not object to exposure to sunshine, but it is when given a cool, sheltered position that it is seen at its best, for in such it remains bright and verdant throughout the year. It likes cool loamy soil, and is easily increased by division.

The pure white flowers are produced so freely in tiny clusters, in spring, as to almost completely cover the carpet of foliage; they are carried on slender stems not more than three inches high, and, as stated, the production of these blooms is continued over a long season. This unpretentious Crucifer is indeed invaluable among alpine plants, and it is also a very suitable subject for use as a ground cover to choice Crocus and Narcissus species.

It has a smaller and more compact relative in H. brevicaulis, but this would appear to be rare, for it seldom makes its way into the catalogues of alpine plant specialists, and whether it is so desirable as H. alpina, I am not prepared to state, for I have had no experience of it. *W.*

PLANTS NEW OR NOTEWORTHY.

FATSHEDERA LIZEI.

This hybrid evergreen is the result of a cross between the Japanese Aralia (Fatsia japonica) and the Ivy (Hedera), hence the somewhat ugly name. It is an interesting subject, and was raised by the brothers Lizé, of Nantes, and sent out about three years ago. Mr. Edward H. Woodall kindly sent two plants of it from Nice, shortly after it was distributed, and from cuttings of these we have now several plants put out in various gardens. I send a photograph (Fig. 196, p. 425) of two planted here about two years ago. These are now over five feet in height, and would probably have been considerably larger but for the severe weather of last February, which damaged the soft, young growths. The leaves are uniform and do not show that variation of shape met with in the Fatsia. They are considerably larger than those of the common Ivy, the shade of green being similar.

The growth is free, and the plant promises to make a tree rather than a bush, but it is as yet too early to venture much regarding its future value as an evergreen tree. At present the young growths have too much of the floppiness of the Ivy, and are rather easily bent, or kinked, by strong winds at their junction with the main stems. They may, however, become more rigid as the plant ages, and growth is consequently steadier. *J. Clark, Scarborough Parks Department.*

SALVIA SPATHACEA.

It might reasonably be expected that the genus Salvia, which consists of several hundred species, should have given us far more decorative and useful plants than has been the case. The number worth growing is small when compared with the strength of the genus.

S. spathacea is, however, well worth a trial as it strikes a new note of colour among the open-air species. It is a native of California; is the Humming Bird Sage of the non-botanical, and the Audibertia grandiflora of Bentham. In 1928 it was by far the most striking species in the bed devoted to Salvias at Kew. With me it survived the winter in the open and has formed strong, erect-growing, handsome plants with spikes of soft red flowers.

It may be briefly described as a strong-growing herbaceous plant from two feet to three feet in height; leaves six inches to eight inches long, broadly ovate, the upper surface crenulate and dark green, and the under surface white. The flowers are borne in a dense spike of many whorls. It is a striking plant in many ways, and if the colour could be improved a little, as it might be by careful selection, for they seem to vary in shade, this Salvia might well take a prominent place in every good herbaceous border.

EUSTOMA SELENIFOLIUM.

The successful planting of the beautiful Eustoma (Lisianthus) Russellianum in the open air, where it has been a source of great attraction as a park bed for several months, has turned attention to this splendid genus of plants, and one wishes to know what other members of the family are like.

Through the kindness of Mrs. Bixby Bryant, of Los Angeles, an opportunity of growing E. selenifolium (Fig. 195), has occurred; it is a plant that has not been in cultivation for many years. This species grows plentifully on Mrs. Bryant's own ranch, and an ample supply of seeds was kindly forwarded in 1928.

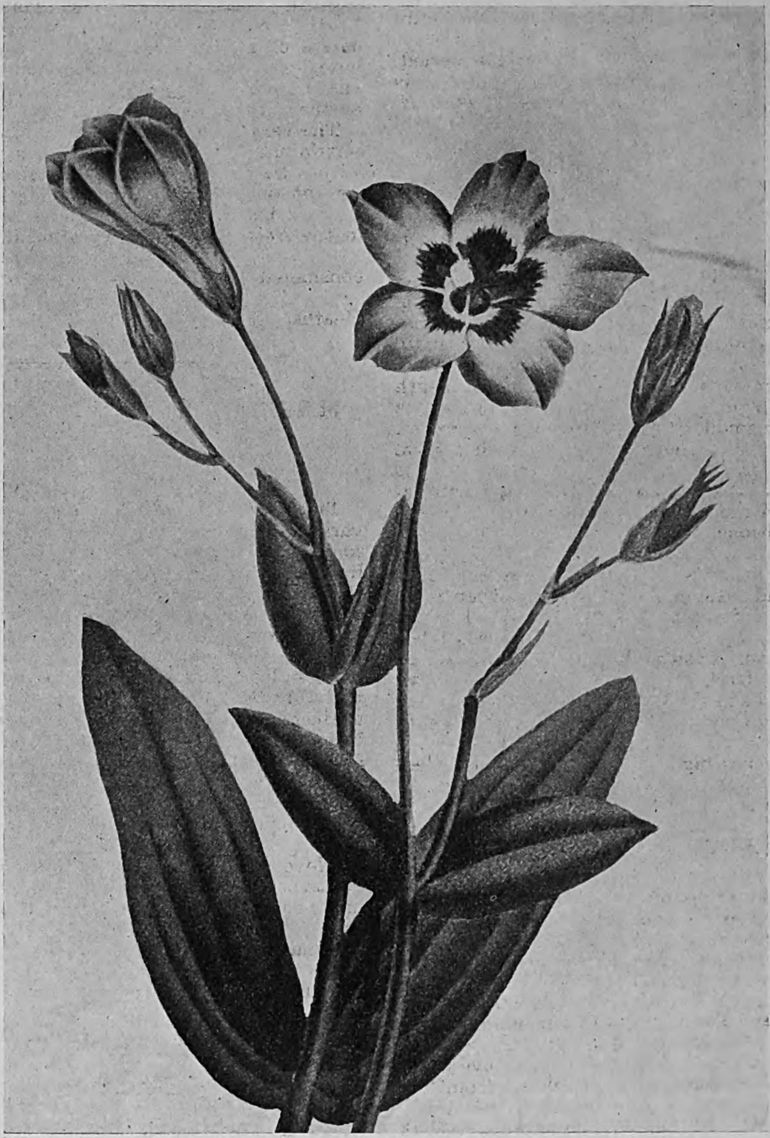

FIG. 195.—EUSTOMA SELENIFOLIUM.

It has not proved any more easy of cultivation than E. Russellianum, in fact, as a park venture it has been more difficult, but at Kew it has flowered very well indeed. While not to be compared with E. Russellianum, it is yet a pretty species and well worth persevering with.

It may be likened to E. Russellianum in miniature, and so requires no further description.

E. selenifolium is very well figured in Paxton's *Magazine of Botany*, Vol. XIII, page 99, as E. exaltatum, where its cultivation, history, etc., are fully recorded. *T. Hay, Hyde Park.*

ORCHID NOTES AND GLEANINGS.

MASDEVALLIAS.

These Orchids are well-suited to an establishment where economy in fire-heat is an important consideration, for most species and hybrids succeed best in a cool house with a minimum temperature of 50°. The temperature must be regular and the atmosphere moist, and, provided due care is given to ventilation, watering and shading, their cultivation is by no means difficult. There are several species of note, but considered from a horticultural point of view, the Masdevallias may be divided into two distinct groups. In one group, the drooping habit of the flower renders the plants particularly suitable for basket culture, while the other section, having erect flowers, are best grown in pots.

For basket culture, M. Chimaera and its variety Roezlii are useful, the type plant being the best. Others are M. Mooreana, M. majestica, M. Chimaera var. Backhouseana and M. muscosa. M. muscosa is an interesting little subject with a lip so sensitive that it shuts up immediately it is touched. Among those recommended for pot culture are such handsome sorts as M. coccinea var. Harryana, M. Veitchiana and M. ignea var. Massangeana.

Owing to their compact habit, a large collection of Masdevallias may be grown in a limited space, and it is possible to have flowers all the year round.

The best times of year for repotting are either the end of August, or February. Plants should not be disturbed unless in need of larger receptacles. In many cases established plants will only require a little fresh compost near the surface. Where, however, potting is absolutely necessary, there is nothing Masdevallias like better than a mixture of chopped Sphagnum-moss, best Orchid peat, and coarse sand in equal proportions, with a sprinkling of fine charcoal or crushed crocks.

Healthy specimens should not be disturbed at the base when repotted, beyond removing any old drainage and sour compost. But where the plants are old and almost leafless, they call for quite different treatment. Such specimens are best divided, and after removing all decayed roots and useless parts, pot each portion separately or several together in one pot. It will be found a good plan to use receptacles of a small size so as to avoid over-potting. Where a light top-dressing will suffice, care should be taken, when removing old soil, not to injure the roots. Plants that have been disturbed will need careful watering for about seven weeks afterwards to prevent loss of roots and foliage. Keep the soil just moist and when more root growth has developed, additional supplies of water may be given. This is one of the secrets of success with Masdevallias, *i.e.*, always keep the roots growing in a comfortably moist compost, without saturating them. Another point to remember is ventilation, for while fresh air is essential, draughts should be prevented, and provided the weather conditions are suitable, bottom ventilation is an advantage. During the summer, shading from strong sunlight and protection from wind will be necessary. When the foliage is well-grown—which is half the Masdevallias beauty—the plants should be examined regularly so as to keep them clean, removing thrips or other pests by sponging the foliage with a good insecticide. *G. B.*

INDOOR PLANTS.

NEPENTHES.

Nepenthes, or Pitcher Plants, are seldom grown extensively nowadays, although anyone possessing a stove or a tropical plant house in which a temperature of 65° can be maintained through the winter months should certainly grow a few of these curious plants.

Their cultivation presents no great difficulty provided a suitable temperature can be maintained and plenty of moisture is afforded both at the roots and in the atmosphere, for without such the plants will never acquire the strength necessary to produce their curious Pitcher-like leaves.

Nepenthes may be raised from cuttings taken early in the year (about the middle of February is the best time), inserted in small pots in a mixture of finely-crushed crocks, sand and chopped Sphagnum-moss, and plunged in a propagating case with a bottom-heat of 75° to 80°. If kept close and shaded, they should root in about two months, when they may be potted into four-inch pots, using a mixture of best fibrous peat, crushed crocks, clean Sphagnum-moss and a little charcoal, care being taken not to injure the tender young roots during the process. Grow the young plants under moderately close conditions until they have become established, when they may be placed close to the glass. Keep them well supplied with water at the roots—the water should be the same temperature as the house—and syringe freely to keep the staging and surroundings thoroughly moist. Some of the strongest plants may require another shift into five-inch pots as the season advances, using for this purpose a compost similar to that for the first potting, only in a rougher state. After the second potting, keep the plants well up to the glass by suspending them from the roof-rafters; light shading should be given and increased as the sun gains power, for if subjected to strong sunlight the leaves assume a deep crimson colour, instead of being tinged or mottled with red; this latter condition is evidence of the robust health essential to the full development of the pitchers, which should be produced at the extremity of every leaf. Every effort should be made to maintain a temperature of 75° to 80° during the summer months, and not lower than 60° to 65° during the winter. The plants, having been properly wintered, should be headed back to four or five buds in February and grown on as advised.

The following are a few worthy members of the family:—N. coccinea has crimson, flask-shaped pitchers with deeply fringed wings, and N. Rafflesiana, a handsome Bornean species, has greenish-yellow pitchers richly marked with brown. The pitchers of N. Lewis Bradbury are large, green, blotched with pale red and with fringed wings; those of N. Ratcliffiana are flask-shaped, green, spotted with red, and with ciliate wings; while N. Sir W. T. Thistleton Dyer has very large pitchers heavily blotched with rich brownish-crimson, with a waved and finely ribbed rim. N. Wittei, another desirable sort, has very long and narrow pitchers, which are green, blotched with dark red, with a small, dark green rim. *J. L. McGoogan.*

BULB GARDEN.

TULIPA CHRYSANTHA.

There are few Tulips suitable for culture in the alpine house, among the most useful being T. chrysantha, which makes an effective, if not brilliant, display over a considerable period in the early spring. I first made the acquaintance of this charming bulb last year at Wisley, where a large pan of some two dozen blooms attracted much attention for about five weeks. The narrow leaves, of a glaucous hue, about five inches long, reflexed, and with a narrow, darker margin, were refined in appearance, while the clear yellow flowers were borne stiffly erect on four-inch stems, and were delicately scented. T. chrysantha appears to be a somewhat variable species in the colour of its blooms. *J. T. Wall.*

MUSCARI POLYANTHUM.

Two or three years ago a friend sent me a few bulbs of this lovely Grape Hyacinth. I planted them in a small group in the rock garden and since then they have made a wonderful show each spring. The colour is a particularly pleasing shade of blue, and the flowers are slightly larger than those of the ordinary Grape Hyacinth. As this colour is not too plentiful in the garden, I am convinced Muscari polyanthum will be found an acquisition to any garden. The bulbs may be purchased now, and they should be planted so soon after they are received as possible.

Well-drained, moderately rich soil is appreciated by this Muscari, and I find it is beneficial to mix a little leaf-mould with the medium at planting time. In addition to its value on the rock garden, the species makes an attractive bed if massed closely in a sunny situation, while as a subject for conservatory and house decoration it is also very useful. The bulbs should be lifted and replanted about every third year. *George H. Copley.*

PLANT VARIATIONS.

(*Continued from p.* 405.)

SPORTS, CHIMAERAS, VARIEGATION AND MUTATIONS.

Bouvardia.

Bouvardia Bridesmaid, a double, pink-flowered variety, when propagated by means of root-cuttings gives rise to double, red-flowered plants, which are indistinguishable from the variety called Double Hogarth. In 1918, out of a batch of seventeen root-cuttings one came single, as in single Hogarth. This single, scarlet variety produced during 1926 a branch with single, pale pink flowers.

The variety Princess of Wales is a variety having single, pale pink or cream-coloured flowers and, when grown from root-cuttings, gives a red-flowered plant, very distinct from the parent.

Pride of Brooklyn, a single, white-flowered variety produced during 1926 a branch on which were white flowers, as in the type, and some pink flowers, as in the variety Priory Beauty, while one flower was half-white and half pink.

Alfred Neuner and President Cleveland have shown a tendency to vary a little from root-cuttings.

Pink Perfection, a large-flowered, pink variety, is stated to have been raised from root-cuttings of President Cleveland (*Gard. Chron.*, Dec. 13, 1919).

The following sports are mentioned by Burbidge: Bouvardia Davisoni, a white sport from Hogarth; Maidens Blush, a blush or pink sport from B. Davisoni.

Phlox decussata (Garden Varieties).

It is well-known that some of these Phloxes, especially those with pink and white flowers, or white flowers having pinkish buds, have a tendency to produce pure white, pure pink, and sometimes various degrees of pink and white flowers. Occasionally, the salmon-pink or even the magenta-pink will vary in purity of colour. When such varieties are grown from root-cuttings, they cannot be depended upon to come quite true to type.

The following varieties grown at Merton from 1923 to 1926, have varied more or less when propagated by means of root-cuttings: Duchess of Roxburgh, Meteore, Mrs. Oliver, Steigler, Fiancé, and Lady Tweeddale.

Of sixteen plants raised from roots of Phlox paniculata var. alba, one has abnormal flowers with peculiar small, crumpled petals which do not expand. This peculiar form remains constant, and can be reproduced by means of its roots but has not produced viable seeds.

The variegated-leaved varieties Comptesse de Jarnac and Phlox Iris versicolor, have given green-leaved plants from root-cuttings.

Other Variegated Plant Chimaeras.

Spiraea Ulmaria var. variegata, a variety having a green skin over a yellowish core, produces from root-cuttings yellowish shoots which soon die owing to the absence of chlorophyll (Fig. 194).

Other variegated-leaved plants, having a white or creamy-skin over a green core, have produced normal green shoots from root-cuttings, *e.g.*, Ajuga reptans var. variegata, Bouvardia Humboldtii var. corymbiflora variegata, Epilobium hirsutum variegatum, Rubus fruticosus var. variegatus, Sedum Telephium var. variegatum, Solanum Dulcamara var. variegatum, S. capsicastrum var. variegatum and Symphytum patens var. variegatum.

Plants in which the variegation is not well defined, *i.e.*, having mosaic, patchwork, or mottled leaves, and when grown from root-cuttings come true to the parental form, are: Artemisia vulgaris var. variegata, Barbarea vulgaris var. variegata, Geranium Endressi × G. striatum, and Pelargonium peltatum variety Madame Guillemond.

Plants having purplish or red leaves usually come true from root-cuttings. *e.g.*, Ajuga reptans var. purpurea, Brassica oleracea (Red or Pickling Cabbage), and Corylus Avellana var. purpurea. Doubtless this would apply generally to purple-leaved forms of trees and shrubs, were it found possible to induce them to produce buds on their roots.

Graft Hybrids.

CHIMAERAS PRODUCED BY GRAFTING.

In addition to the chimaeras which occur in many variegated plants and hybrids, others may be artificially produced by grafting. These are commonly known as graft hybrids.

In making a graft hybrid, the main shoots of young and vigorous plants of the two species concerned are cut off and exchanged by grafting the one upon the other. The form of grafting which has proved most suitable for this purpose is that known as "cleft" grafting. After a union of stock and scion has taken place, the plants are cut across at the point of union, and the tissues exposed on the cut surface. After a time, a callus is produced on the cut surface giving rise to young shoots. Most of these consist of uniform tissue which is pure for one or the other of the species used, but from parts of the surface, where the two tissues have united, will occasionally arise shoots combining the tissues of both kinds of plants forming the graft.

These shoots may be either (A) Periclinal Chimaeras, or (B) Sectorial Chimaeras. In the former the core of the shoot will consist of the tissue of one of the species, enclosed within the skin of the other, and may be likened to a glove fitting over and completely hiding the other kind. Such chimaeras are often distorted in appearance and the leaves much buckled. The leaves of such chimaeras are usually all alike and more or less intermediate in shape between the two species of which the composite cross-grafted plant is composed. When these plants produce viable seeds their progeny reproduce only the character of the tissue forming the sub-epidermis. In Sectorial Chimaeras the shoot will consist of a sector formed of tissue of another species type. Such a plant will have three types of leaves, some of the type of one species and some of the other and a few that are sectorial.

The sectorial leaves form in the region of the stem where the tissues of the two kinds meet, the two parts being divided by a longitudinal line.

Where the differentiation of the two types of tissue, however, is not so definite, and when the stripe of tissue consists of a few cell layers of another species, such a chimaera is not a true sectorial, but is actually closer to the periclinal form of chimaera, and is best regarded as an incomplete periclinal, for which the name mericlinal has been proposed. The large majority of plants hitherto mentioned in literature as "sectorials" really belong to this group.

Mericlinal chimaeras are quite common, sometimes as whole plants, often only as shoots, or even as flowers or fruits.

Graft hybrids have been known a comparatively long time, and as the name indicates, were first believed comparable to a seminal hybrid, formed by the actual fusion of cells of stock and scion, and were regarded as real hybrids, in that the parental elements were supposed to have fused or conjugated in the same way as the male and female cells in fertilisation, but in many graft hybrids which have been investigated, it is clear that no nuclear fusion occurs.

In the well-known graft-hybrid, Laburnum (Cytisus) Adamii (*Gard. Chron.*, 1911, Vol. L, Fig. 77), the skin of the plant is formed by Cytisus purpureus; the central portion or core, by the common Laburnum, but a re-arrangement of the two tissues frequently occurs and gives rise to the development of pure shoots of Cytisus purpureus and Laburnum, respectively.

This interpretation was first given by Baur and followed up later by Bateson and others, especially in regard to variegated plants, in which it became evident that a large number had a chimaerical structure.

Although many chimaeras, as stated above, are exceedingly stable, yet a tendency to "break" or "sport" is, on the whole, a characteristic feature of such plants.

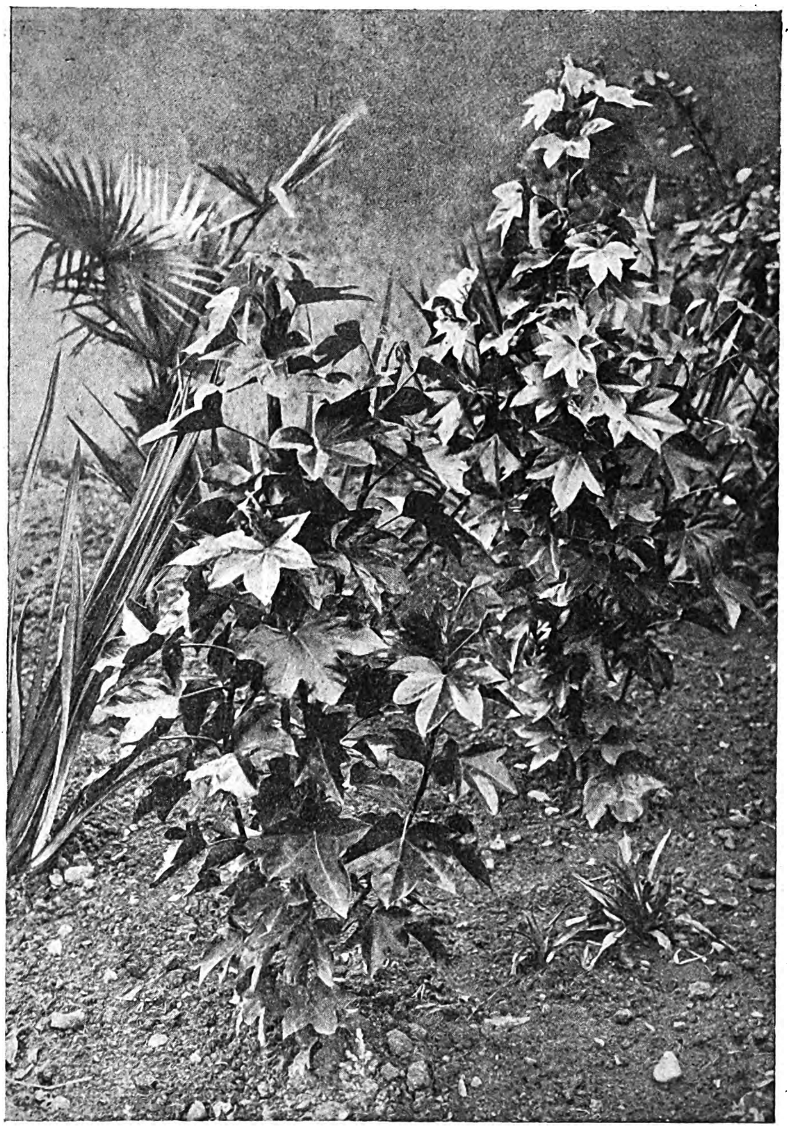

FIG. 196.—FATSHEDERA LIZEI.
(see p. 423.)

It will be understood from the foregoing account of the general make-up of chimaeras that neither from sexual reproduction nor from vegetative propagation, whether from shoots or roots, will anything genetically new be produced. The breaking or sporting only gives back the constituents of the plant either separated out, or rearranged.

Among examples of periclinal and sectorial chimaeras produced by grafting—space will not permit of a fuller discussion of this interesting subject—the following well-known kinds of graft hybrids may be mentioned: Laburnum Adamii or Cytisus Adamii, produced by grafting Cytisus purpureus on Laburnum vulgare, by Jean Louis Adam, a nurseryman at Vitry, near Paris, in 1825. This plant is often met with bearing branches of Laburnum vulgare and small, twiggy bunches of Cytisus purpureus, together with branches having flowers of a more or less intermediate character, *i.e.*, Laburnum Adamii.

Crataego-Mespilus Dardari, *i.e.*, Mespilus germanica (Medlar) grafted on Crataegus monogyna (Hawthorn), was first noticed in 1894-5 in the garden of M. Dardar, at Bronveaux, near Metz.

Crataego-Mespilus Asnieresii occurred also on the same tree. Both these graft hybrids tend to break up in the same way as Laburnum Adamii has done. (Bean, *Kew Bulletin*, 1911, p. 269; Gregory, *Gard. Chron.*, 1911, Vol. L, pp. 161 and 185, Figs. 86 and 87).

Crataego-Mespilus grandiflora (syns. Mespilus Smithii, of De Candolle, and Pyrus lobata, of Nicholson) is probably a natural hybrid. It is stated to occur as a wild plant in France.

Crataegus Oxyacantha, crimson variety, when grafted upon the white form, will produce bunches of white, pink and crimson flowers.

Fagus sylvatica var. heterophylla (Fern-leaved Beech), when grafted on the common form, frequently produces branches of both forms, intermixed.

Various species of Solanum and Lycopersicum (Tomato) have been grafted with interesting results; first by Professor Winkler, of Tubingen, 1908 (Sclanum tubingense, *Gard. Chron.*, 1911, Vol. L., Fig. 76), and more recently by Jorgensen and Crane (see Bibliography to follow). *A. Hosking, Garden Superintendent, John Innes, Horticultural Institute, Merton, Surrey.*

(To be continued).

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

NOW is the time to scatter seeds of the Willow Gentian—G. asclepiadea—on bare ground in woodland. The seeds are produced in great profusion and germinate readily. Flowers follow in the second year after sowing, ranged along three-feet wands; most of them blue, although here and there a plant with white flowers will appear. Rabbits do not injure this or any other species of Gentian.

Another good woodland plant is one which has long been here under the name of Chelone obliqua; but I am doubtful whether that is its proper title, for some authorities give purple as the colour of its flowers; whereas those of our plant are pink. It produces plenty of seeds. Add to this pair Antholyza paniculata, and you have a good trio to brighten woodland glades withal in autumn.

As for Montbretia, one should be careful where it is planted, for it is a terrific spreader, smothering all humbler growths and spreading with resistless rapidity. Similar discretion should be observed in planting the pretty Polygonum campanulatum. Seduced by assurance that it was not a rampant grower like P. cuspidatum, P. sachalinense, etc., we treated it as a border plant, whence it has given us much trouble to expel. Even in the woods, discretion is desirable in assigning it a place, for it races around as greedily as any of the others. What is the secret property in all species of Polygonum that deters rabbits from nibbling the succulent shoots?

Most species of deciduous Rhododendrons turn a fine colour in autumn. Conspicuous among the Azalea group in this respect is R. Schlippenbachii, which carries its broad, rounded leaves in terminal whorls of five, and these assume most delicate tints before they fall. A large bush of this species presented a sight as fascinating in October as it was in May when covered with roseate blossoms.

Among loftier growths that give as fine autumnal colour, Zelkova crenata and Z. acuminata deserve to be more frequently planted that it seems they are, for the foliage turns rich yellow and orange before falling, and outlasts most other deciduous trees in doing so. Just now, near the end of November, it is about at its brightest. It is attractive at all stages of growth, but in planting it should be borne in mind that these species of Zelkova are not shrubs, but nearly related to the Elm and attain a stature of a hundred feet.

This question of stature sometimes causes embarrassment, as when we had a lot of Cercidiphyllum seedlings to deal with. Being ignorant of the nature of this beautiful tree, we treated them as shrubs for the beauty of their autumn colouring, and found, too late, that it is the largest deciduous tree in Japan! The ultimate proportions of Eucryphia pinnatifolia seem likely to exceed what we expected of that beautiful species. The largest specimen I have seen is at Poltalloch, in Argyll. It is twenty-nine feet high and eighteen feet across; proportions whereof the slow growth of this plant in youth gave one little indication. *Herbert Maxwell, Monreith.*

NOTES FROM A WELSH GARDEN.

A GALE of great violence, following a period of frost and wet in trying alternation, was enough to bring most of the autumnal colouring to an abrupt ending. But two young trees braved the ordeal so successfully that they scarcely lost a leaf, and are now (mid-November) better than ever. These are Liquidambar styraciflua and Eucryphia pinnatifolia. The former is, perhaps, the more brilliant in its blended shades of orange, crimson, plum-red and vivid rose-carmine, but there is a singular attractiveness in the Eucryphia's warm and generous tones, and these seem to harmonise with the tree's stately poise and balance. I saw nothing finer in seasonal leaf-colour at Bodnant the other day than this splendid Chilian, represented by a great number of well-matured specimens admirably grown, but some Fothergillas were, perhaps, the most brilliantly adorned among individual smaller shrubs.

A Cheiranthus called, I believe, C. Newark Park, has been a remarkably striking plant throughout the summer, and it is still bearing quite a good number of blooms. These latter are an unusual fulvous orange-brown, which strikes just the right note in the autumn border. The plant, moreover, has a compact habit and vigorous constitution to add to its reputation for continuous blossoming. Its fiery colour is not one that goes well with anything, but on a dry, sunny slope mainly occupied by a few groups of some of the taller Sedums, with a good deal of gold, red and yellow about their flowers, fruits and leafage, C. Newark Park has been, and is still, most effective.

Until this season, Dahlia Merckii was new to me, save by name, and from what I had heard of it, I was not unprepared to be disappointed with the performance of a bunch of seedlings sent by a generous correspondent. But these have been, on the contrary, most delightful. Although only a couple of inches high in June, they grew rapidly, attaining one foot by September when the first blooms appeared. These flowers, if small as Dahlias go, were in nice proportion to the size of the plants, and their colour was a most refreshing shade of cool and delicate lavender. I write in the past tense, for at the first frost, a week or so ago, the plants were completely cut down. But this Mexican, which is by no means a new thing, is stated to be quite reasonably hardy. If the colour varies in seed-raised plants, it is evident from the above experience that this is a species which will repay selection. The very similar Bidens dahlioides (Cosmos diversifolius, *Bot. Mag.*, t. 9180), by the way, never reappeared after last winter's severe frosts.

A plant which is always a source of much satisfaction and pleasure at this season is that form of Vinca difformis (acutiflora) with starch-white blossoms, the sharply-pointed segments of the corolla being broad, almost rhomboidal, in shape. This may be, and probably is, the type, but it is a vastly superior plant to that dismal creature whose flowers are a sombre purple of insufferable dullness, with the lobes of the blossoms so mean and narrow that they are reduced to mere strips. The former is also a much better bloomer, giving flowers in abundance during mild intervals from November to May.

Salvia Grahami is a useful old plant for autumn flowering. If it often falls short of being among the first-raters, owing to its leisurely and economical habit of opening only about one flower of a spike at a time, its season covers at least six months. The colour of the blossoms seems to vary somewhat, but the brilliant crimson, warmed by a touch of scarlet in some lights, of the sub-shrub at its best is decidedly attractive. With this and the faithful Winter Jasmine (Jasminum nudiflorum) which breaks into yellow in November, must be mentioned Abutilon megapotamicum. Few flowering shrubs so doggedly carry-on throughout the late autumn as this semi-evergreen species with its gay shuttlecocks of blood-red and yellow bobbing at the ends of their hair-like stems. Viburnum fragrans is, of course, another regular autumn bloomer, but I always feel that it might make a more successful job of its flowering were it to defer the process until spring. For its gift of fragrance we can at any time afford to be grateful, but Apple-blossom effects in November fog or winter's grey are rather on the chilly side, and the shrub places a mortgage on its future by indulging in these spasmodic efforts with such a careless disregard of conditions.

Callicarpa japonica and C. Geraldiana are pleasing little shrubs at this season, even if their crop of shiny violet berries is too frugal to be very striking. They may do better in other places, but here a certain shy reticence in growth, so well as in flower and fruit, militates against real success. The big violet fruits on some of the hardy Dianellas can, on the other hand, be the showiest objects of their colour throughout the autumn, and they appear to be able to withstand light frosts with impunity. How many of us wish we could make that last statement of the Berberises! Most of them, certainly the great majority of those species and hybrids grown for autumnal display, are so susceptible to frost that the colour of their beautiful fruits is transformed into most disagreeable hues at the first touch of frost. Even the intensified splendour of the foliage is not sufficient to make amends for that depressing failing. It is very different with the Cotoneasters. But if the earliest fruits of these have almost all gone—and the later ones are not yet ripe—we still have our well-tried friend, C. Simonsii, and I am not angling for sensation when I write that one specimen of this fine and useful shrub is at the moment by a long way the most handsome of its genus in a fairly representative collection. C. Simonsii will always vary a good deal in its autumnal display according to its position and treatment, but when you get it laden with its very large orange-scarlet berries and almost every leaf aglow with a flaming crimson, I know of no other mid-season species that will even rival it. Moreover, few species known to me give this colour over so long a period, for it is among the first to redden, and spring will be within sight before the last of its berries have gone. Its only failing is the absence of that symmetry and grace which is so characteristic of its genus.

The woodland undergrowth's contributions to the passing autumn cannot be passed over, for there is a peculiar charm in the rust-red, cinnamon-brown and buff of the Osmundas, our native species bravely excelling in stature, if not always in colour, the Americans. Onoclea sensibilis is not less delightful in its soft fawn than it is in summer, and the rambling green masses of Dicksonia pilosiuscula pass away in a chrome-yellow. Among such things as these are the stately growths, nearly a yard tall, of an almond-scented Solomon's Seal, its glossy black fruits dangling in the wan light of its ivory leaves. That equally elegant plant, Lysimachia clethroides, adds its note to autumn's requiem in a swan-song of pallid creamy-white and vivid rose-madder, and the blood-red of Geranium Loweii, leaf and branch, is even more intensely rich here beneath the trees than is the dying foliage of G. sanguineum in its various forms in drier, more open places. *A. T. Johnson, Ro Wen, Conway.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXVI.—Sadiya Calling.

Buttercup and I had often discussed what it would feel like to live normally again, after pigging it for eight months. To be clean and dry, to feel overfed, to sleep between sheets, to have room to swing a cat (under cover, of course; there was room to swing a cat in the forest), to move swiftly from place to place, to see humanity in bulk, and vegetation in bulk, to hear sounds more alluring than the rasp of the wind in the trees, the drumming of rain on the tents, and the muffled whine of the torrent—how pleasant it would all be. That to which we looked forward ardently was Civilisation, and this life, throughout October particularly, was just hell! But to enjoy the full flavour of the contrast, one ought to fly to Calcutta; otherwise the change was too gradual, a slow convalescence. There was the first bungalow at Theronliang. Then Denning Outpost, where one could buy a tin of sausages, and perhaps a chicken. Finally, Sadiya, and the Political Officer's bungalow, followed by a hot bath, and a boiled shirt. And so by easy transition to Calcutta, a sea voyage, and home. Still, although we did not fly to Calcutta, in the end I made a very rapid march back to Theronliang. On October 25, I was buffeting my way through a snowstorm on Polon. At 7 p.m. on the 29th I marched into Theronliang bungalow, an hour after Buttercup arrived, faint with hunger and weariness, having done seven hard marches, mostly in pouring rain, in four days.

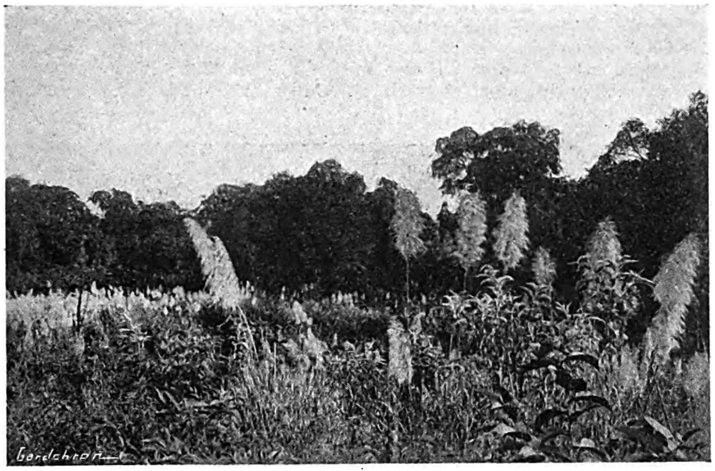

FIG. 197.—FEATHER GRASS (SORGHUM SP.) IN FOREST CLEARINGS.

I had never intended to exceed the speed limit like this, and it came about in the following way. When last heard of, we had abandoned the cave on Polon, and started down hill in the rain. From our late camp to Mitonma took about three hours, by a ridge I had only explored for a short distance. When we reached the temperate forest below I noticed all kinds of trees—a Magnolia with small, squat cones, a magnificent specimen of M. rostrata, the yellow 'Grande' Rhododendron in full fruit, a tree with shining digitate leaves and tall spikes of black berries (Araliaceae), R. arboreum, the 'Stamineum' Rhododendron and others. I regretted then that we had not explored this ridge in the spring; but how *could* one tell! Our object then had been to push on towards the head of the valley with as little delay as possible, and Mitonma was not one of the places where we had been held up.

Then, crossing the deep ravine we had turned aside from the main path and followed a bye-pass to the next village; and having spent the night there, we departed early for Chibaon, where I half expected to meet Buttercup. However, we learnt that he had left two days previously, and therefore had not halted a day. I picked up a note from him, and some supplies and started in pursuit—he would be leaving the bridge at this time, unless he had halted a day there. It is two long marches for coolies from Chibaon to the bridge, although without loads the Mishmis do it in a day. We went down to the river bed, where I saw Peach trees in full bloom, and then started on the toilsome journey along the cliffs and over boulders. It had been a fine morning, and was quite pleasantly hot in the river bed. On the forested cliff I found a remarkable parasitic flower, springing directly from a root, just like a Rafflesia. There were lots of them about, and I dug up several—the colour was reddish, and reddish-chocolate within, the seven fleshy petals being curved back.

By the time we reached our old halting place it was raining steadily. We stopped for a meal, and presently along came Buttercup's porters from the bridge, bringing with them a note. He had started down the Lohit, so evidently he had made a good bargain over the coolies, and was going through to Theronliang without a halt.

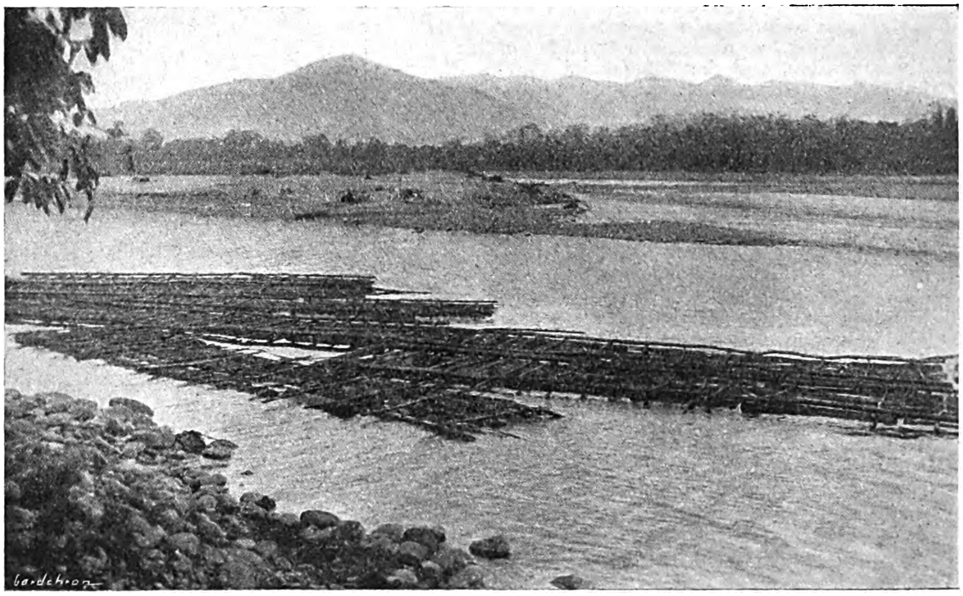

FIG. 198.—TIMBER RAFTS ON THE LOHIT RIVER.

After lunch we started again in pouring rain. It was an awful march. Towards dusk we came to the long cliff climb, and here we had to hurry, as the ledge was very narrow, and there were several dangerous places which would have been difficult to negotiate in the dark. By the time we got on to the boulders in the river bed again it was almost dark, for the sky was overcast and darkness came early; but we pushed on in the rain, and reached the bridge. We had still some way to go to the village, up a steep path. The night was inky dark, I was almost dead beat, and the rain was coming down in sheets. However, we reached the village, exhausted after marching for eleven hours, and I was soon asleep.

Next morning the Lohit valley was full of cloud, and it was quite evident that it would not stop raining all day. At first I thought of staying in the hut, but about 10.30, I decided to start and get it over. So we marched till five o'clock, when we reached the river bed camp, not nearly so pleasant now as it was in April, when the weather had been fine. Buttercup had spent the previous night here—he was only one march ahead now—and we occupied the Banana-leaf shelters his men had run up. I hardly thought it possible for us to reach Theronliang next day, so did not make a very early start. In 1926, when we had marched from the Delei to Theronliang in two days, we had camped a good bit further on than this the first night; on the other hand, we had coolies with us then, carrying full loads. We started again in a drizzle of rain, but it improved later. About one o'clock, we reached Buttercup's last camp, and halted for a quick lunch.

Then on again, until at last we reached the saddle, and dropped down into the Tidding valley. There were still two hours of daylight left, but the worst part of the march lay ahead; over the boulders, through the waterlogged forest, until finally we came to an appalling cliff, and my men lost the proper track. However, men had been over the cliff before, so we supposed we could go. Towards the top, I lost my nerve completely, and said I could not go on. Hubble was above me, climbing like a monkey; the Gam was below. Another wall of rock barred the way, and only a root cable to haul myself up by, with a 150 feet fall into the roaring river if the cable broke, or my grip failed. After collecting myself a bit, and deciding that it was more terrifying to go back than to go on, I pulled myself up the face, and found that we were at the top, and also on the path—which we ought never to have left. From here to the Tidding bridge was some distance, and the going was not good; but there were no more cliffs. We reached the bridge after dark, crossed the river, and had only another mile to go. It was just like 1926, history repeating itself almost word for word, except that now I knew the way!

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; September 7, 16, 28; October 12, 26; November 9 and 23, 1929.

Presently the lights of Theronliang glimmered ahead, and crossing the torrent, we climbed the high bank and shouted. Next minute Luso came out, astonished to see me, and I walked into the bungalow to be warmly greeted by Buttercup, whom I surprised laying out the packets of Rhododendron capsules.

He had not yet dined, so we had as good a dinner as we could beat up—although it hardly differed from our usual camp dinners, as the resources of Theronliang were no greater than those of the Delei valley. There was also a big mail. We talked until late. Buttercup had arranged for coolies to take us to Denning, but we decided not to move until the 31st, as we were both in need of a rest and the seeds, or rather fruits, were in need of drying.

It was still raining next day (October 30), but as we were in a comfortable bungalow, that did not much matter. In the afternoon, the sun came out for an hour, and we got some of our things dried. Our intention was now to march through to Denning in a day—about twenty-three miles, with an ascent of 4,000 feet on our side, and a descent of nearly as much to Denning. We started the coolies off early, and ourselves followed leisurely. The last marches always seem the longest, and it was a vile day, drizzling steadily, so that we had no view from the saddle. At Dreyi, just over the top, we halted for lunch, then continued downhill. Late in the afternoon the clouds rolled back, and the sun shone out; so I collected some plants—Strobilanthes, a ground Orchid with prettily-veined leaves (Odontochilus ?) and a purple-flowered Teucrium. There was nothing else of note in bloom except the common white Porana racemosa, and here and there in the forest a pink cloud of Peach blossom.

Before dark we reached Denning, and went straight off to the canteen in the fort, where we bought some tinned provisions. That night we all had a square meal. Having established telephonic communication with Sadiya, we learnt that owing to the heavy October rains, the Political Officer could not come out and bring us in, as it was impossible to get his car across the swollen Digaru river. We had therefore to march another twenty-two miles, cross the river by boat, and meet the car on November 2. Our kit was loaded on to three bullock carts, and as the carts could not do more than ten or twelve miles a day, we marched only so far as Teju the next day, and slept the night there. On the 2nd we covered eleven miles to the Digaru, which we crossed by dug-out; but the coolies waded across thigh deep, carrying our kit, the carts being unable to cross. Another mile brought us to Sanpura, where we had lunch while waiting for the Political Officer.

The forest was not particularly interesting at this season. On the outward journey the most conspicuous trees had been Erythrina indica, and Bombax malabaricum, both of which were leafless and in full bloom; Duabanga sonneratioides was also in bloom. Now the only trees in flower were Terminalia myriocarpa, and the small Bauhinia purpurea with white flowers. Another common tree I noticed along the road was Sterculia villosa, which was shedding its big Acer-like leaves—the only semi-nude tree in sight. Here and there a Talauma (T. Hodgsonii probably) was recognised by its large leaves and wooden fruits.

The Digaru, although shallow, was very wide, the milky water flowing swiftly, so that it had not yet been possible to throw a trestle bridge across. We soon reached the bungalow on the other side, one cart with our immediate necessities having come along at a good pace; so that when, about two o'clock, the P. O. turned up with his car, the kit was immediately loaded on to the carrier, the running boards, and elsewhere. Among the 'immediate necessities' was a large, awkward-looking Naga basket, filled with Orchids and with the pseudo-bulbs of the Gamboge Primula collected on October 25, which were to catch the home mail.

We were now only twenty-four miles from Sadiya, and the big car took little more than an hour to cover the distance, in spite of two ferries, and so ended the Mishmi Hills Expedition. *F. Kingdon Ward.*

THE GENUS PRIMULA.

(Continued from p. 405.)

STRICTA (Hornem.). Rigid P. (Farinosae).

A very dwarf perennial species from sub-arctic Europe, closely allied to P. farinosa, with a compact rosette of non-mealy leaves three-quarters-of-an-inch to one-and-a-quarter inch long, with oval-lance-shaped, pointed or blunt, usually entire blades gradually tapering to winged stalks equalling or shorter than the blade. Flower stem erect, three to nine inches tall, bearing an umbel of three to eight purple or violet-coloured blossoms. Corolla about three-eighths-of-an-inch across, with heart-shaped, almost entire or slightly notched lobes; tube cylindrical, about twice as long as the calyx. Flowers in June and July. Introduced in 1882.

Grows in damp, rocky pastures on the mountains of Norway, Sweden, Lapland and northern Russia.

Culture: As for P. farinosa.

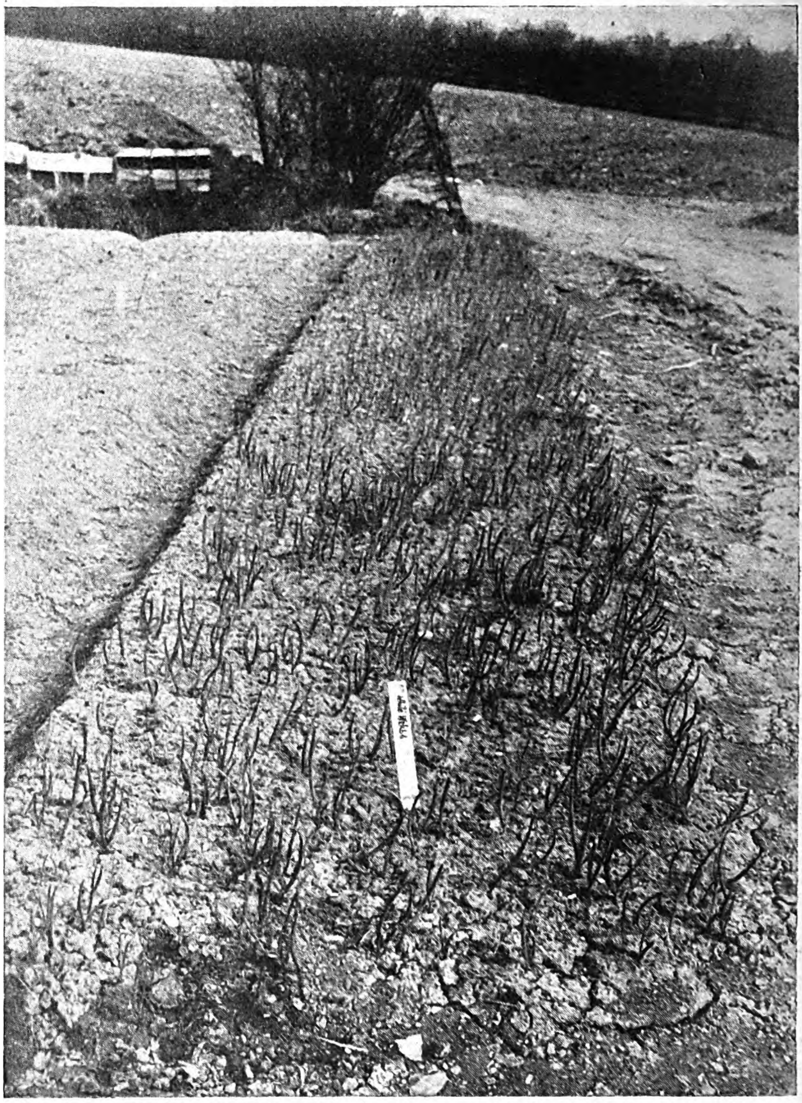

FIG. 199.—AUTUMN-SOWN ONIONS: WHITE WELSH.
(see p. 429.)

STRUMOSA (Balf. f.). Purple-leaved P. (Nivales).

A handsome perennial species with a tuft of a few leathery or somewhat fleshy, more or less erect leaves, three or four inches long, with broadly lance-shaped, blunt or rounded blades, tapering at the base to an erect, winged stalk sheathing below at the rootstock; margins somewhat cartilaginous, edged with irregular, rounded teeth; both surfaces more or less covered with very minute, glandular hairs, non-mealy, the upper surface tinted deep purple. Flower stems four to seven inches tall, dark purple, covered with golden meal upwards and bearing an umbel of about eight nodding, yellow blossoms with an orange or deeper yellow eye. Corolla about three-quarters-of-an-inch across, with oblong or nearly round, bluntly toothed lobes; tube cylindrical, slightly dilated upwards, twice as long as the calyx, with a ten-lobed ring in the mouth.

Grows in damp, alpine pastures near Champa Pumthang, in the Bhutan Himalayas, at about 14,000 feet above sea-level.

Culture: As for P. sikkimensis.

STUARTII (Wall). Stuart's P. (Nivales).

A handsome, deciduous, perennial species, with large tufts of somewhat leathery, lance-shaped, blunt leaves four to five inches long, tapering to winged stalks, dilated and sheathing at the base where they are surrounded by leaf-like scales; margins edged with small, sharp teeth; upper surface more or less smooth, underside coated with yellow meal. Flower stem robust, nine to twelve inches tall, bearing a many-flowered umbel of fragrant yellow blossoms, on stalks about half-an-inch long. Corolla concave, nearly one inch across, with rounded, entire or slightly toothed lobes; tube funnel-shaped, twice as long as the calyx. Flowers in June and July. Introduced in 1845.

Grows in swampy mountain pastures in the Nepal and Sikkim Himalayas, at about 13,000 feet above sea-level.

Culture : Plant it in good, rich, somewhat heavy loam and peat, and treat as a bog plant when in growth.

SUBTROPICA (Hand.-Mazz.). Sub-tropical P. (Obconica).

A small-flowered, little-known species with a tuft or rosette of broadly-oval or rounded, nearly entire, papery leaves, heart-shaped at the base, from one inch to three inches long; upper surface clothed with short, jointed, rust-coloured hairs, underside glaucous and densely covered with stalked glands; nerves covered with long, jointed, rust-coloured hairs. Flower stem slender, hairy, three to six inches tall, bearing an umbel of seven to fourteen pale rose-coloured blossoms on stalks about a quarter-of-an-inch long. Corolla about a quarter-of-an-inch across, with broadly heart-shaped, deeply cleft lobes; tube about as long as the calyx. Flowers in May.

Grows in the shady places among shrubs, near Beyendjing, on limestone formations, in Yunnan, at 5,000 feet above sea-level.

Culture : As for P. obconica. *A. W. Darnell.*

(*To be continued*).

AUTUMN-SOWING VARIETY OF ONION RESISTANT TO FROST AND WHITE ROT.

DURING the course of an investigation into the relative resistance of different varieties of Onions to the disease known as white rot (Sclerotium cepivorum, Berk.), the writer has come across one variety of autumn-sowing Onion which has proved itself to be not only fairly resistant to white rot for three successive seasons, but also extremely resistant to frost, particularly during the past winter season, 1928-29. This variety is named in England White Welsh; in France, Ciboule Commune Blanche; in Germany, Winterhecke Zwiebel. Strange to state, it is not a variety that is usually listed in English seedsmen's catalogues, but two different samples of seed of it were specially obtained through a Manchester seed warehouse, along with seed samples of four other varieties including the well-known and extensively grown White Lisbon Onion. This latter, although undoubtedly a variety *par excellence* for salad purposes, is, unfortunately extremely susceptible to white rot, and also rather tender to frost.

Losses estimated at upwards of fifty to sixty per cent. of the crop, due to white rot disease alone, have been found by the writer to be quite general on many intensively cultivated market gardens. Consequently, the present investigation has been undertaken partly at the request of several large market growers in Lancashire and Cheshire, to ascertain, *inter alia*, whether any other more resistant but equally serviceable variety, or varieties, exist in commerce to supplement or replace the popular White Lisbon variety. The six selected seed samples, representing varieties considered suitable for testing and comparison after preliminary trials, gave quite satisfactory germination percentages in the laboratory tests, the White Welsh No. 2 sample in particular showing ninety-two per cent. and the No. 1 sample seventy-six per cent. viable seeds. All the samples were eventually sown between July 30 and 31, 1928, at two centres, one in north Lancashire, and the other in mid-Cheshire, on ground previously tested and found to be fairly uniformly and badly contaminated with the white rot disease. At the centre in north Lancashire the seeds were sown broadcast in plots of 130 square feet each, while at the centre in mid-Cheshire they were sown in drills, the drills being about forty yards long and ten inches apart.

On September 10, 1928, all the varieties, except the two lots of White Welsh, had germinated and brairded well. It had been noted by the growers at each centre that the White Welsh seedlings were much slower in appearing above ground compared with the others, and seemed to make little or no top growth at first. On December 17, there was again the same striking difference in the average height and general appearance of the White Welsh seedlings: indeed, they were rather disappointing. However, on March 26 and 27, 1929, after several weeks of severe frost—the lowest recorded temperature on the ground having been 4°F., equal to 28° of frost—it was found that all the varieties at both centres had practically succumbed, except the two lots of White Welsh plants, which appeared to be quite unaffected and perfectly strong and healthy, and firmly established in the ground. In fact, although the ground at both centres was severely cracked and fissured and the surface slightly upraised owing to the action of the frost, the White Welsh seedlings were clinging most tenaciously to it, and on closer inspection were found to possess an unusually widespread, deep and strongly developed, fibrous root-system.

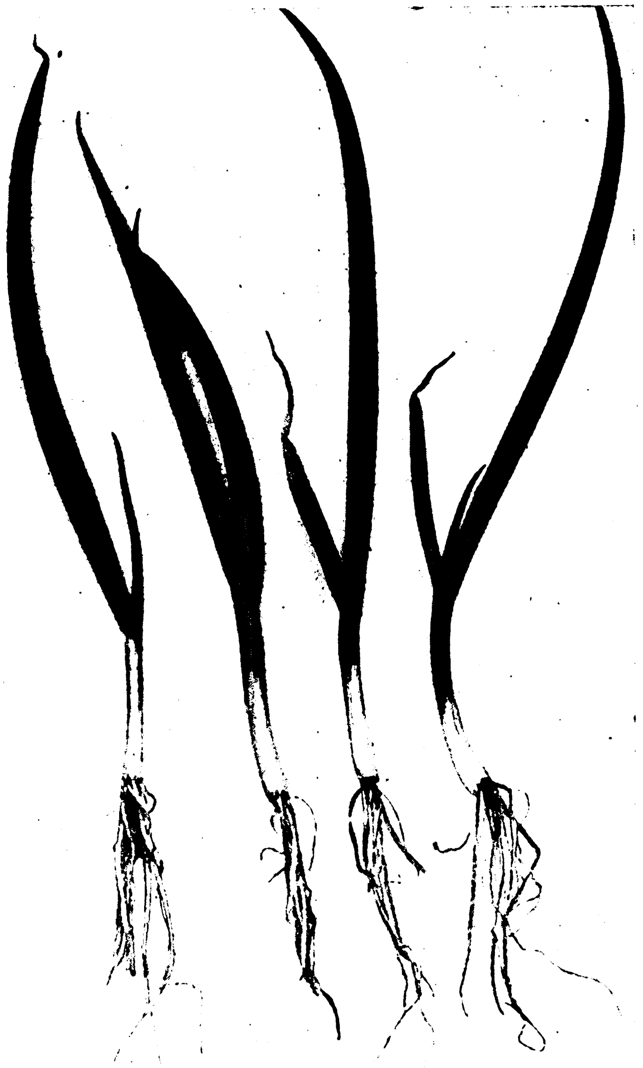

FIG. 200.—AUTUMN-SOWN ONIONS: WHITE WELSH.

About three weeks later, on April 15, 1929, they were found to have made much more rapid and steady growth and to be exceptionally strong and healthy. The accompanying illustration (Fig. 199) shows the general appearance of the seedling plants in one of the plots at the Lancashire centre on April 15, 1929, while four of the same seedlings carefully uprooted to demonstrate the extensive and vigorous character of their fibrous root-system are shown in Fig. 200. On May 17, 1929, after a spell of warm and showery weather, a few of the plants—roughly, about two per cent.— were found to be slightly attacked by white rot, and when the whole of the plants were ultimately pulled and bunched on May 20, 1929, it was noticed that the most severely attacked plants exhibited a distinct pink or dull reddish coloration in the outer epidermal region of the leaf bases and bulbs, and were obviously under-developed and inclined to run to seed. On the other hand, it was observed that the least attacked plants not only possessed the well-developed and vigorous root-system already mentioned, but also more or less pure white leaf-bases and bulbs of moderate dimensions and attractive oval shape. Fig. 201 illustrates this distinction quite clearly.

From such observations it would seem as if there were two different strains of the White Welsh variety of Onion, and that possibly, when carefully separated out and seeded, the white strain might prove most useful for growing alongside plots of White Lisbon as a stand-by or alternative variety in the event of unusually severe winter conditions prevailing, or should the land be badly contaminated with white rot. It has also been suggested by the growers that in the case of broadcasted plots of this variety, fine earth should be strewn among the young plants when they are about four inches high, so as to raise the general level of the soil surface and produce a more extensive blanching of the leaf bases, or, in the case of drilled plots, that the soil should be drawn up to the plants in the rows, since the blanching prevents the tissues from becoming green and tough and makes the young Onion plants more attractive and valuable for salad purposes. In conclusion, it may be mentioned that from the 130 square feet plot referred to above and illustrated in Fig. 199, about 204 bunches of salad Onions were pulled, and that owing to the prevailing scarcity of the White Lisbon variety through frost damage, upwards of one shilling per dozen bunches was realised for this lot of White Welsh Onions on the Blackburn market on May 25, 1929. *E. Holmes Smith, B.Sc. (Edin.), Advisory Mycologist, The University, Manchester.*

HOME CORRESPONDENCE.

The Need of Education for Gardeners.—Two very interesting letters have recently appeared in your columns under the above heading. Unfortunately, neither of the writers permitted himself to go far beyond pointing out the need for education, and offering sundry encouragements to the studious young gardener. Mr. Cuthbertson tells us (p. 371) that the right type of young men are not being attracted to the profession in sufficient numbers, and cites as The reasons the very low standard of remuneration and a dislike of country life. This statement, I believe, is not quite in agreement with the experience of many of your readers. That remuneration is not in proportion to the long training and arduous study that success demands few will deny; but that the right type of young man is not attracted in sufficient numbers is, I think, a premature conclusion. I suggest that the lack of available facilities for education is responsible for the seeming dearth of talent in the profession. I do not refer to general education, but to education in those branches of science which facilitate the application of practical experience gained by the gardener in the course of his work. Probably Mr. Kennedy-Bell (p. 330), or Mr. Cuthbertson, would commend—I almost wrote condemn—the young gardener to a study of text-books written on such subjects. Apart from the question of expense, there are very few suitable text-books to be had, and those that do exist are not sufficiently well-known among young gardeners. Besides, the study of text-books does not form a connected and graduated form of education suitable for all ages and all types of mentality; the majority being far too involved for beginners. Night school for the young gardener as a medium of education may be practically ruled out. His work mainly lies in places where his attendance at a good night-school would necessitate long journeys, often up to ten miles, to an industrial centre where such classes are held. Even then, suitable subjects are rarely taught. Apart from inaccessibility, such things as duty intervene to prevent the young gardener from attending evening classes regularly. From night school we turn to consideration of the various colleges and science institutions which cater for the requirements of the gardener. The gardening profession draws its youth largely from the lower-paid portion of the artisan class, and a course of instruction at such an institution, extending over a period of one or more years, presents a financial problem quite beyond the means of the vast majority of young gardeners. I am not in a position to write of the efficiency of the majority of these colleges, but from my knowledge of the equipment and routine of one which serves a wide area, I have come to the conclusion that the tuition provided is far from adequate. Had Mr. Cuthbertson stated that the right type of young man was not attracted to these colleges, I believe there would have been far more truthful evidence on which to base such a contention. Of the "stick in the muds," of which we are invited to believe ninety per cent of the gardening profession is composed, there is no lack of evidence to show that a large number of them are quick to answer to a sense of competition if that spirit is properly fostered. We have but to look at the many exhibitions of garden produce held all over the country, and picture the very high standard of excellence displayed. That standard is not maintained without a keen sense of competition among gardeners, young and old. We frequently hear of a gardener possessed of show fever. Why is a similar fever so rarely generated by the technical side of his profession? The numerous societies which cater for the practical side of horticulture have long ago learned the value of competitions and publicity, but when they attempt to cater for our technical requirements, these lessons are practically forgotten. How many young gardeners know of the advantages (if there are any) of possessing R.H.S. Certificates or Diplomas, or how many have any knowledge of the standard of proficiency necessary for the obtaining of such distinctions? Beyond a statement in a gardening paper that the necessary information may be had from the secretary, and a brief publication of the names of the successful students, the parent horticultural society does next to nothing to popularise its examinations. Why is not such information forwarded to all whom it may concern in the same way in which show schedules are broadcast. Horticultural science has advanced by giant strides in recent years, but the passing on of the knowledge gleaned has not kept pace with what has been achieved in this direction by other professions. Consequently, young men of a studious disposition who enter trades or commercial careers to-day have a distinct advantage over the "True Sons of Adam," apart from the accessibility of evening tuition at properly organised and conducted classes. I refer to the great advantages which such men can and do derive from postal tuition. Those in doubt of the efficiency of such tuition have but to watch the results of the various Board of Trade or City Guild examinations, and discover the part played by the various correspondence colleges in the preparation of many of the most successful students. Is it too much to ask that the Royal Horticultural Society seriously considers the advisability of compiling and running correspondence courses fitted to prepare students for the examinations held by that body? Such a policy should prove a wonderful advertising medium, bringing the Society into direct touch with thousands of young gardeners. Financially, I can see no insurmountable barrier to such a system. A reasonable charge could be fixed for a complete course of instruction, even payment on the instalment system could be arranged. Nor need the Society have any qualms about entering into competition with existing correspondence colleges, for a series of courses compiled and conducted by experts from every branch of horticulture and allied sciences would be quite unique. A pronounced step taken in this direction would mark a new era in the relations between the Royal Horticultural Society and the many gardeners and garden lovers who still remain outside its influence or appeal. Moreover, it would do much to foster that sense of competition which alone can account for the salvation of that ninety per cent. which I feel sure are also attracted to other walks of life. While quite agreeing that the studious young gardener will always work his way to the best positions, I feel that much remains to be done to mitigate the arduous nature of his climb up the mountain of knowledge. *R. Bain, Kingston Hall Gardens, Derby.*

Lonicera nitida.—No reader having responded to my request (p. 75) for information as to soil and treatment to ensure flowers and berries on this shrub, may I appeal to *H. A. P.* (p. 371) to give us the benefit of his experience, if his plants have flowered and fruited at any time. If they attained to seven feet in height, one possible factor would seem to have been present. *C. Nicholson, Tresillian, Cornwall.*

——It was encouraging to read the note on this plant by *H. A. P.*, in your issue of November 9 (p. 371). My own experience confirms that of the writer as to its hardiness. The last two winters have been exceptionally severe, but young plants of Lonicera nitida never lost a leaf, despite the fact that they had been planted only a few days when the first severe frost of 1927 fell upon them. It is a much more hardy hedge plant than the Golden Privet, for the latter has suffered severely each winter, losing all its leaves and many shoots. One can readily believe that it will largely supersede the Privet as a hedge plant, not only on account of its beauty, but because of its ease of propagation. Not only will every tiny shoot root readily, but large, woody growths dibbled into sand, and placed in a warm house or frame, root in an astonishingly short space of time. Some of these large cuttings, placed in sand in a Cucumber house, sent out roots all along the portion of stem buried, and also masses of aerial roots to an inch above the sand. For comparison I put in large cuttings of the Honeysuckle and Golden Privet, together, during the summer. The former rooted, were hardened off, and are now in position in the hedgerow. The Privet has not yet formed a root. The Honeysuckle can be layered successfully. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

Prunus Pissartii Fruiting.—I have this week picked a fruit of Prunus Pissartii, and as I think this happens but rarely here in north Northumberland, I am anxious to know whether this tree has been recorded as producing fruits so far north before. *S. S.*

Linaria alpina.—Your correspondent, *L. B. C.*, writing about Linaria alpina (p. 364), seems unduly to magnify the difficulty of growing this charming little plant. I have grown it for three years, starting with one plant, and this year I have consigned hundreds to the rubbish heap, as it seeds itself about like Chickweed. I started it in the moraine, but it has now spread to all parts of the rock garden, and is rapidly making a nuisance of itself. The first year I saved seeds and found no difficulty in germinating them in pans. My soil is a light, sandy loam. In view of its readiness to seed, I take no precautions to save the plants through the winter. Saponaria caespitosa I also find comes very readily from seeds. *R. Ginns, Dernford, Desborough.*

The New Forest.—Being a native of Ringwood, on the western border of the New Forest, and well acquainted with some parts of the latter, I should like to thank you very much for your leading article dealing with the New Forest in your issue of November 16. It is an extremely fascinating place, which all nature-lovers, I think, whether natives or not, soon learn to love. I would, however, point out that the Scots Pine is native in the forest, quite apart from the enclosures (plantations), and therefore is a natural feature which should not be suppressed, no matter how much the plantation mania of the Forestry Commission may be deprecated. *C. Nicholson.*

Coloured Raffia and Begonias.—An unusual and rather disturbing experience attended the use here of green Raffia on winter-flowering Begonias of the Gloire de Lorraine and Optima types, and it may be of some interest—and, perhaps, a timely warning—to your readers if I recount the details. The plants were staked and tied in the usual way with ordinary white Raffia until some few weeks ago, when it occurred to me, in view of the fact that many of them would be required as specimen plants for decorating, the substitution of green tying material would assist in giving a better "finish," and consequently I procured a small quantity from a local sundriesman. I ought, perhaps, to explain that I went to a local shop, in preference to the usual firms of horticultural sundriesmen, as the quantity required was negligible, and to save the unavoidable delay necessitated when ordering by post. The Raffia was used in due course, and in less than a week the points of various plants were seen to have dropped down as though they had been broken nearly off, but not severed clear, and on closer investigation it was found that the coloured Raffia was the cause of the trouble. Practically every shoot secured with this material was found—more or less—to be affected. Some varieties, notably Mrs. Petersen, were in the advanced stage of being "eaten" through (this seems to be the only expression that aptly describes the phenomenon), but all varieties—including the stouter-growing Optima—were affected. Certainly the latter was not so badly affected as the varieties of the Gloire de Lorraine group, but the brown "rust-like" markings on the stems proved conclusively what would have been their fate also, had the Raffia been allowed to complete its devastating work. The only theory I can advance is that there must have been some sort of acid applied to the material—either accidentally or in the colouring process—when being dyed, that caused the mischief. Has any reader had a similar experience, or is anyone able to throw light on the cause? I have used green Raffia on many previous occasions—happily, with more satisfactory results—and on a variety of subjects, but I shall be loath to employ it for Begonia tying again. *T. W., Shugborough.*

Sempervivella alba.—This plant, the subject of M. Correvon's enquiry (p. 382), is figured in the *Bot. Mag.*, t. 8,985. In the accompanying text by Dr. Otto Staft, it is stated that, although the origin of the plant in cultivation is not precisely known, Sempervivella alba appears "to be identical with a plant not uncommon, as Mr. J. S. Gamble informs me, on the mountains around Simla. This plant was originally (1846) described as Sempervivum album, by Edgeworth, who had collected it at Kranda, Simoor (?). I have not been able to trace exactly the locality Kranda given by Edgeworth for his Sempervivum album, but internal evidence points to its being in Simor or one of the adjoining Simla Hill states." *W. T. Stearn, Cambridge.*

Preservation of Dahlia Roots.—The excerpt, on page 379, from *The Gardeners' Chronicle* of Seventy-five Years Ago, is, as ever, very interesting. But how the Dahlia appears to have improved; or should it be deteriorated? Or, again, is it the present-day gardener who has improved or deteriorated, as the case may be? No longer do we find it essential to preserve the Dahlias fibrous roots with the greatest care, nor do our plants require constant nourishment when in a dormant state. Dahlias appear to have degenerated into coarse-fibred things which survive, retain, and develop their "nascent buds" if lifted from the ground, almost immediately after the shoots have been cut off, and placed in the store. So far from immediately covering the fibrous roots of the tubers with sand or earth, some of us, in our ignorance, have placed the Dahlias upside down for a time beneath a greenhouse staging, to the utter destruction of these so essential fibrous roots! And our Dahlia tubers have lived to produce good flowers another year. *A. C. B.*

FRUIT GARDEN.

THE FRUIT STORE.

THE surroundings of both Apples and Pears in the store should be fresh, sweet and clean. A musty atmosphere is bound to be reflected in the flavour of the fruits, and while a low temperature is desirable to maintain a long season of maturity, an equable temperature, either high or low, is even more to be preferred. By that, I mean, Apples stored in a uniform temperature of 45° have kept quite as perfect and retained their flavour better than those stored in a temperature of 33°. The only difference was in date of maturity, those kept at the higher figure matured earlier and their season of table quality was considerably shortened. Fluctuations of temperature affect keeping qualities, and temperatures too low affect table quality. Hence it is that many gardeners who store at the lower temperature draw from the store a week's supply of dessert fruits at one time, and place these fruits in a warm vinery or on a shelf in the Melon house to bring out that flavour and aroma which are so desirable.

The greatest factors, however, in the successful storage of hardy fruits are, to grow fruits free from insect and fungus damage, care in gathering, and gathering at the proper time, for if gathered prematurely, shrivelling invariably follows.

The Food Investigation Board's report for the year 1928 has just been issued, and, as usual, contains a valuable amount of information. In dealing with the effect of temperature and other factors on the storage of Apples, the report states: "One outstanding result of importance to plant physiology is the discovery of a 'climacteric' (critical period) in the life of the Apple. It occurs at maturity and is marked by a large increase in the rate of respiration, a change in character of respiration, which is indicated by an alteration in the ratio between the amounts of carbon dioxide given off and of oxygen taken up, and by the rapid production of these chemical substances which confer upon the fruit its flavour and aroma." One of the most interesting problems under investigation at present is stated to be the significance of the stage of maturity of the fruits when gathered. This is known to have a profound effect upon their keeping qualities.

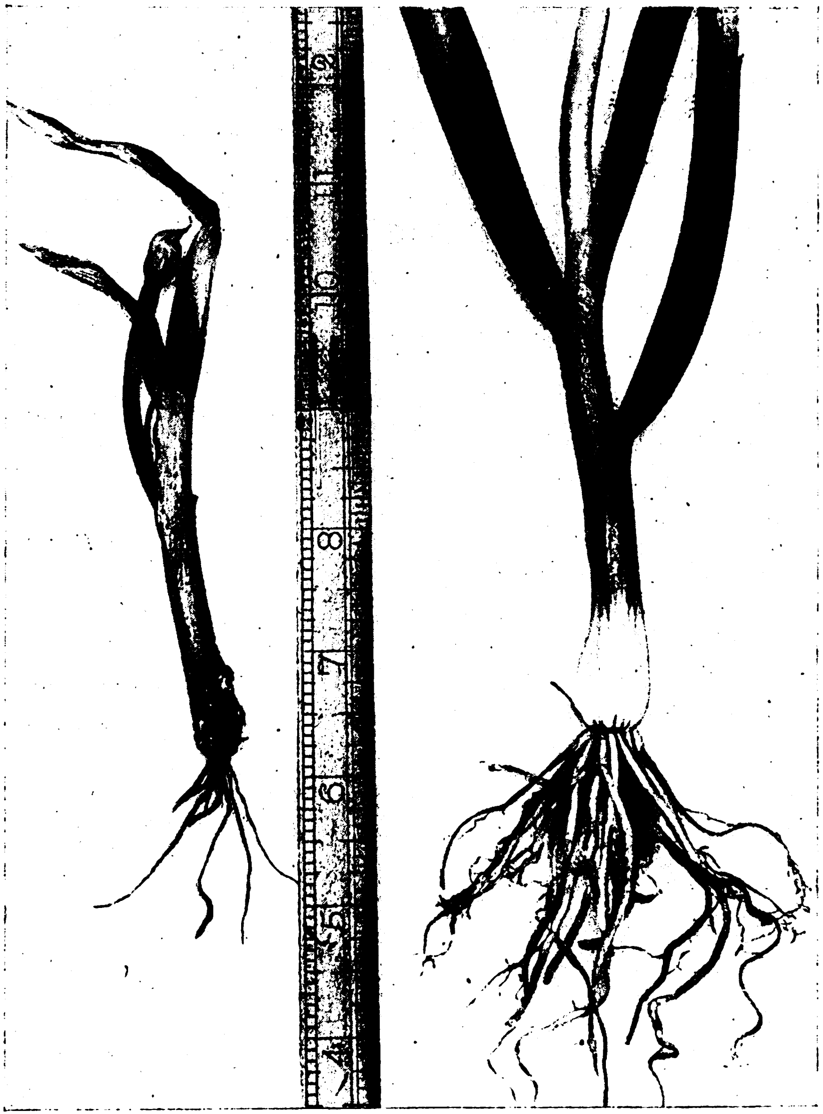

FIG. 201.—AUTUMN-SOWN ONIONS.
Showing diseased plant (left) and clean plant (right).
(see p. 429.)

That light should be excluded from the fruits in store is an injunction which has been handed down from the earliest times. But I do not know of any experiments carried out in this country bearing on the point of why darkness is so essential. Some years ago, however, Messrs. Revière and Pichard, of France, carried out some experiments, and the results of these were published in the French *Journal of Horticulture*, a summary of which was published in *The Gardeners' Chronicle* of August 27, 1921 (p. 107). A note or two from this summary may be of interest.

The experimenters state that where the object of storing fruits in the fruit room is to delay its maturity, darkness is important. The authors, on November 27, commenced experiments with two small lots of the Apple Calville Blanc, exposing one to diffuse light and the other to darkness. On February 12 of the following year, only those fruits which had been exposed to diffuse light were ripe. Those which had been left in darkness were not ready until several weeks later. Analysis of the dark-kept and the light-kept fruits showed that whereas the total sugar content had decreased in both, it had decreased considerably more in the light-kept Apples than in those maintained in darkness. This is in conformity with what the plant physiologist would expect, namely, that glucose is the sugar which is used up in the course of respiration. It would seem to follow that respiration of fruits such as Apples is appreciably more rapid in light than in darkness, and that light would, in some circumstances, be a useful aid in speeding up the ripening process.

In *Modern Fruit Growing*, by Mr. Seabrook, Chelmsford, the author, commenting on the storage of fruits, states: "Apples grown in grass or partial grass are notoriously better fitted for storage than Apples grown under highly manured or forced conditions. . . . . . Apparently the dominating factor is a low nitrogen content and more fibre. Also Apples from mature trees keep much better than those from young trees; small and medium-sized Apples keep better than large, coarse, ill-finished ones." *H. H. Cook.*

SOCIETIES.

NORFOLK AND NORWICH HORTICULTURAL.

This is the centenary year of the Norfolk and Norwich Horticultural Society, and the Society has celebrated this event by holding three large shows—a Spring Show, a Summer Show and an Autumn Show. The summer show was a big affair, and, as reported in these pages, it included the provincial show of the National Sweet Pea Society. On the occasion of the Autumn Show, held on November 21, 22 and 23, in the spacious and beautiful St. Andrew's Hall, and its corridors, it entertained a deputation from the National Chrysanthemum Society in the person of Mr. Charles H. Curtis.

The exhibition was a fine one, competition was unusually good, and the quality in every section reached a very high level, but especially in the classes for Single Chrysanthemums, Pears and vegetables.

Groups and Plants.

Only one group of Chrysanthemums was staged, and to this bluntly conical exhibit the first prize was awarded; popular Japanese, Incurved, Single and Decorative varieties were included, and Coleuses, Ferns and Dracaenas were used to furnish the base of this exhibit from the Parks Department of the Norwich Corporation

Competition was quite good, however, in the pot plant classes. For three Japanese varieties, in pots not exceeding ten inches in diameter, the Norwich Corporation Parks Department led with freely-flowered examples of Jean Pattison, Rose Day and Blanche de Poitou, C. C. Bond, Esq., coming second, and including in his set an excellent example of Mrs. Keith Luxford.

For three plants, distinct varieties, of Single Chrysanthemums, the Norwich Corporation Parks Department again led, showing Juno, White Model and Laddie; the second prize fell to J. R. Imrie, Esq. (gr. Mr. G. Fowler), New Catton; and the third to E. C. Bond, Esq.

Among miscellaneous plants, Cyclamens were best shown by Colonel H. G. Barclay (gr. Mr. W. G. Barrie), Colney Hall, who also showed the best Chinese Primulas; W. T. F. Jarrold, Esq. (gr. Mr. A. E. Wood), Beeston St. Andrew's Hall, had the best Primula obconica and the best P. kewensis, and Miss E. M. Hacker (gr. Mr. J. King), Great Ormesby, the best P. malacoides, finely flowered. Salvia splendens was best shown by the Norwich Corporation Parks Department—fine big plants, while the Misses McLintock (gr. Mr. G. R. Wright), The Grove, Norwich, led for Begonia Gloire de Lorraine, and E. J. Edwards, Esq. (gr. Mr. E. R. Matthews), led in the class for any other Begonia, with B. Clibrani.

Cut Blooms.

Four competitors came forward in the class for three dozen Japanese blooms in not fewer than eighteen varieties, on boards. The premier set was shown by the Lowestoft Corporation Parks Department, the best blooms being those of Charles Davis, Lady Miller, W. Rigby, Mrs. G. Drabble, Mrs. J. Gibson, Louisa Pockett, Miss A. Ellis and Red Majestic; second, Mrs. H. Thompson (gr. Mr. F. Wiles), Middleton Hall; and third, Mrs. Barker Hahlo (gr. Mr. A. Bentley), Langley Park. Apparently there was but one entry of twelve Japanese blooms, and this, deservedly awarded the first prize, came from Mrs. C. M. Hacker (gr. Mr. J. King), whose best flowers were of W. Rigby, Yellow Majestic, Mrs. H. Wells, Mrs. G. Drabble, Louisa Pockett and Red Majestic.

The Lowestoft Corporation Parks Department led in the class for thirty-six Japanese blooms, shown in vases; this set was a good one and consisted of Mrs. R. C. Pulling, W. Rigby, Louisa Pockett, Princess Mary, General Petain, Mrs. G. Drabble, Mrs. J. S. Kelly, Madame O. J. Guillot, Queen Mary, Dawn of Day and Barbara; second, Mrs. Barker Hahlo.

The finest Japanese blooms in the show were found in the class for eighteen blooms, in six varieties, shown in vases, and here the Norwich Corporation Parks Department (Superintendent Captain Sandys-Winsch), excelled itself by winning the first prize and the N.C.S. Silver-gilt Medal, with superb flowers of Victory, Louisa Pockett, Majestic, Princess Mary, Thomas W. Pockett and Mrs. G. Drabble; the flowers of Victory were unusually fine. Second, the Misses Colman; third, Mrs. C. M. Hacker.

The Norwich Corporation Parks Department was successful in winning the premier award for six vases of sprays of Japanese Chrysanthemums, with Rose Chocod, Captain Kettle, Jean Pattison, Theresa, Madame L. Valet and Ra; second, the Lowestoft Corporation. The best six vases of sprays of Single Chrysanthemums were staged by the Norwich Corporation Parks Department, and the varieties shown were Edith Dimond, Juno, Fairy, Hon. Edith Smith, Mona and Mrs. T. Hancock; second, the Misses Colman; third, Brig.-Gen. Sir T. Jackson (gr. Mr. H. Aldis), Herringfleet Hall, Lowestoft.

First prize for eighteen varieties of Singles, three blooms in each, in vases, was won by the Misses Colman (gr. Mr. A. Gulvin), Carrow Abbey, Norwich, with quite good flowers of J. Palmer, Walter Howe, Bob Greenfield, Kitchener, Susan, Isabel Felton, Sandown Radiance, Mollie Godfrey, Mrs. Harry Woolman, Red Molly, Fantasy, Alert, Hon. Edith Smith, Mrs. E. Page, Miss A. Wisby, Edith Dimond and Bronze Molly; second, the Lowestoft Corporation Parks Department (Superintendent Mr. G. H. Smart); third, Miss H. Thompson (gr. Mr. F. Wiles), Middleton Hall.

There was fine competition in the class for twelve varieties of large Singles, three blooms of each, in vases. There were five entries, and the premier award was won by Major A. L. Bruce (gr. Mr. W. C. Dean), Brooke Hall, Norwich, with glorious blooms of Miss A. Wisby, Red Molly, Susan, Mrs. W. E. Hutchinson, Kitchener, Margaret, Supreme (very fine), Bronze Molly, Isobel Felton, Juno, Robert Collins and Molly Godfrey; second, Bertram Hall, Esq. (gr. Mr. F. A. Double), Blundeston; third, Mrs. Barker Hahlo. The premier set in this class contained the finest Singles in the show, and it was awarded the National Chrysanthemum Society's Silver Medal by the N.C.S. Deputation.

In the miscellaneous cut flower classes, Carnations and Violets were well shown, Colonel H. G. Barclay leading with the former. An interesting class was one for sprays of berried shrubs. Colonel H. G. Barclay led for six kinds with fine examples of Stranvaesia Davidiana var. undulata, Cotoneaster frigida, Celastrus articulatus, Euonymus radicans var. variegata, Viburnum Opulus and Berberis subcaulialata.

The decorative section was well filled, but as almost every exhibitor had chosen either yellow or very light bronze flowers, the general effect was somewhat monotonous. The leading prize-winners were Major A. L. Bruce, for a large hall vase; and Miss M. C. Palmer, for a basket, with Mrs. Sandys-Winsch, second.

Fruits.

Fruits are usually shown in fine condition at Norwich, and there was no falling off in this section on November 21. Nearly fifty classes were provided, and in most of these the competition was excellent.

Mrs. Barker Hahlo exhibited the finest set of nine varieties of dessert Apples, showing clean, good-sized and highly coloured examples of Wealthy, Cox's Orange Pippin, d'Arcy Spice, Charles Ross, Laxton's Superb, Ribston Pippin, Blenheim Pippin, American Mother and Allington Pippin; second, the Hon. W. K. Rous (gr. Mr. T. Simpson), Worstead House, Norwich.

J. A. Christie, Esq., M.P. (gr. Mr. S. High), Framlingham Pigot, Norwich, led for six varieties of dessert Apples, and G. E. White, Esq. (gr. Mr. T. Ludkin), Eaton House, led for three varieties.

The Hon. W. K. Rous won first prize for nine varieties of culinary Apples, and Mr. C. D. Wigan a similar honour for six varieties.

Among classes for special varieties, Mr. C. D. Wigan (gr. Mr. F. W. Wilby), led for Allington Pippin, and J. Kennington, Esq. (gr. Mr. W. Palmer), Surlingham, led for Charles Ross.

A splendid collection of nine varieties of Pears, five fruits of each, won first prize for Lord Suffield (gr. Mr. A. J. Jones), Gunton Park, Norwich, in a keen competition. His set consisted of grand specimens of Beurré Alexander Lucas, Doyenné du Comice, Beurré Dumont, President Barabe, Durondeau, Marie Louise, Pitmaston Duchess, White Doyenné and Charles Ernest.

J. A. Christie, Esq., M.P., scored a fine win in the class for a collection of six varieties of Pears, five fruits of each, showing splendid examples of Charles Ernest, Emile d'Heyst, Durondeau, Easter Beurré, Winter Nelis, Doyenné du Comice and Prince Napoleon second, the Hon. W. K. Rous.

Lord Suffield led for six bunches of Grapes, winning with good clusters of Muscat of Alexandria and Lady Downes; the same competitor led for three bunches of Alicante Grapes, and showed the best collection of twelve varieties of fruits, in which Pears were a fine feature. Lord Suffield had the finest Doyenné du Comice Pears, the best dish of Marie Louise, and the best dish of Glou Morceau. Major Rous and J. M. Christie, Esq., M.P., were also successful exhibitors in these single-dish classes.

Vegetables.

The vegetables displayed in the several classes provided for collections were good, and there were frequent surprises in quality of those staged in single-dish classes, where Leeks, Celery, Brussels Sprouts, Parsnips and Beets were presented in quantity and unusually fine quality.

In the classes for collections of vegetables, the most successful competitors were the Hon. W. K. Rous, Mrs. Barker Hahlo, Mrs. D. H. Lane and G. C. Lang, Esq. (gr. Mr. T. Sheldrake), Great Plumstead Hall, Norwich.

Commercial Fruits.

A large exhibition of fruits, chiefly Apples, was set out in the Blackfriars Hall. This was arranged for the purpose of demonstrating the successful cultivation and packing of fruits for commercial purposes in East Anglia, and it fulfilled that purpose. In regard to cultivation and colour the samples were excellent, while in packing there was evidence of much care and skill.

Some of the principal prizewinners in this section of the show were Colonel Petre, Westwick; Miss Cannell, Lodden; Mrs. Blofield, Mrs. S. Rope, Broom Fruit Farm, Mr. A. Foord, and the Colton Fruit Farm.

GLASGOW AND WEST OF SCOTLAND.

At the Annual Meeting of the Glasgow and West of Scotland Horticultural Society, held on November 6, Mr. Isaac Fleming, Director of Parks, Paisley, presided over a crowded attendance of members. The Directors reported that there was an increase of 1,173 entries at the Autumn Show, and that the membership had increased by 45 to 812, while the financial statement for the past year indicated a balance of revenue over expenditure amounting to £107; the invested funds were valued at £361, and the cash assets, £332. In the course of the discussion on the reports, complaint was made by several members with regard to a condition in operation at the September Show, whereby the deposit of 2s. 6d. paid by competitors was forfeited if all the entries were not staged. The income from that source amounted to £18 7s. 6d., and it was pointed out that the rule was not in operation by any other Society. There were seventeen candidates for the seventy-three vacancies in the Directorate, and a card vote resulted as follows:—Nurserymen: Messrs. John Cairns, Thomas Dagg, Alexander McAlpine and T. B. Kerr. Gardeners: Messrs. Isaac Fleming, James Cuningham, Alexander Davidson and A. T. Harrison. Amateurs: Messrs. D. Cowell, John Bell, Thomas Nelson, J. H. McDonald and Donald Gunn.

BRITISH CARNATION.

November 20 and 21.—The thirty-seventh show of this Society, which was held in the Horticultural Hall, Vincent Square, Westminster, was one of the most successful winter shows the Society has held. A large display of Carnations could not be expected, but there were exhibits in each of the fifty-seven classes, and in many the quality of the blooms reached an exceptionally high standard. In addition to these competitive exhibits there were several excellent trade displays of Carnations which, with some miscellaneous floral exhibits, garden sundries and paintings, helped to make a bright and interesting show. Seven novelties were submitted for award, but only one was found to be sufficiently worthy of recognition. On the evening of the first day a most successful dinner was held at the Restaurant Frascati, Holborn, where the large company was entertained by witty speeches and a pleasantly varied musical programme.

First Class Certificate.

W. H. Wallace.—This is an excellent novelty, quite distinct in its deep salmon colouring from any other greenhouse Carnation. The flowers are well-formed, of good size, have plenty of substance, and are carried erect on sufficiently long, stout stems. The only quality of the ideal Carnation that the variety lacks is that of perfume. This splendid novelty was raised by the late Mr. W. H. Wallace and shown by Mr. W. E. Wallace, Eaton Bray.

Open Classes.

There was not the usual competition for the *Daily Mail* Challenge Cup, which was offered this year for the best scented Carnation not in commerce prior to 1927. There were only two entries, and the Cup was again awarded to the deliciously fragrant variety Mavis, shown by Messrs. Walter Hemus, Ltd. Blanche, a good large, white variety, shown by Messrs. Engelmann, Ltd., did not, on the day, emit fragrance to any noticeable extent.

Only Messrs. C. Engelmann, Ltd., staged twenty-five blooms each of seven varieties, and theirs was a splendid exhibit well worthy of the Monro Challenge Cup which was awarded. The varieties were Maine Sunshine, Sunny, Laddie, Red Laddie, Ivory, Mrs. W. Hemus and Citron. Of the two exhibits of twelve blooms of each of any three British novelties, shown in separate vases, the better was by Messrs. Allwood Bros., who showed Rapture, Wivelsfield Apricot and Guy Allwood. Messrs. C. Engelmann, Ltd., were second, with Sunny, Hebe and Blanche.

Only two competed in the class for fifty blooms of Laddie—and the American Carnation Society's Challenge Cup was won by Mr. E. Pulbrook with splendid blooms; Messrs. C. Engelmann, Ltd., were a good second. The three vases of one hundred blooms each of any one variety made an imposing display, and the best set was of superb blooms of Laddie, shown by Messrs. C. Engelmann, Ltd.; Mr. E. Pulbrook was second with Spectrum of good quality. Only Messrs. C. Engelmann, Ltd., showed a vase of fifty flowers in four varieties, and they were awarded the first prize for beautiful blooms of Maine Sunshine, Red Laddie and Topsy. Magnum, shown by Messrs. H. T. Mason, was the best of six exhibits of a vase of twenty-five blooms of a British-raised Carnation not yet in commerce, and Messrs. Walter Hemus, Ltd., were second, with Lassie. Topsy was shown by both exhibitors in the class for twenty-five blooms of any fragrant crimson variety, and the first prize was awarded to Messrs. C. Engelmann, Ltd., for splendid blooms, with Messrs. H. T. Mason close competitors.

Only Messrs. C. Engelmann, Ltd., set up twenty-five blooms each of three distinct colours, and they were awarded the first prize for handsome blooms of Laddie, Improved Ward and Startler. In each of the following colour classes twelve blooms of a distinct variety were required. Ivory, shown by Messrs. C. Engelmann, Ltd., was the best white, with Arctic, shown by the same exhibitors second, and White Pearl, shown by Messrs. Allwood Bros., third. Laddie is undoubtedly the best light pink variety, for it was shown by Messrs. C. Engelmann, Ltd., who were first, and by Messrs. Allwood Bros., the second prize winners. The best medium pink Carnation was Gladys, and Rapture was second, both being shown by Messrs. C. Engelmann, Ltd. Betty Lou, by the same exhibitor, was the only deep pink variety shown. Messrs. H. T. Mason had, in Spectrum, the best red variety, and Red Laddie, set up by Messrs. Engelmann, Ltd., was second. Topsy was shown both by Messrs. Allwood Bros., who were first, and by Messrs. H. T. Mason, who were second, in the class for a crimson variety.

Circe Improved, shown by Messrs. C. Engelmann, Ltd., was the only variety in the class for any purple, mauve or violet variety, and it was well worth the first prize which was awarded. The best vase in the class for any yellow or yellow-ground Fancy was of richly coloured, Maine Sunshine, and Wivelsfield Buttercup, staged by Messrs. Allwood Bros., was second. Chintz was the only variety shown in the class for any Fancy other than yellow ground; Messrs. Allwood Bros. were first, and Messrs. C. Engelmann, Ltd., were second, although the positions were reversed in the class for a vase containing a bloom of each of twelve colour classes. Maud Allwood, well shown by Messrs. Allwood Bros., was first, and a good vase of Sunny, staged by Messrs. C. Engelmann, Ltd., was second in the class for twenty-five blooms of apricot and yellow shades.

Messrs. Allwood Bros. were first in the class for two boxes of Carnation blooms as packed for market and sent by rail. Their box of Chintz was very fresh and beautiful. Messrs. C. Engelmann, Ltd., who were second, were awarded the Silver Challenge Cup in the class arranged to test the keeping qualities of Carnations.

Amateurs' Classes.

On this occasion there were only two exhibits of twelve Carnation plants, and both illustrated first rate cultivation. The first prize was awarded to Lady Emsley Carr (gr. Mr. J. T. Doe), Wonford, Walton-on-the-Hill, for sturdy, well-flowered specimens of such varieties as Betty Lou, Red Laddie, Topsy, Spectrum and Nero. Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, was second, with taller plants which, in a month's time, will be of great merit. His chief varieties were Canadian Pink, Mrs. Hamilton Fellowes and Mary Allwood.

In the class for a decorative arrangement of not more than one hundred cut Carnations on tables measuring six feet by three feet, Samuel Wallrock, Esq., was an easy first, with an artistic display of good blooms in gilt baskets and vases arranged on black velvet and with appropriate foliage. Lady Emsley Carr was awarded the second prize for what was merely a collection of exceedingly good blooms set up in the R.H.S. show vases with no attempt at "decorative arrangement."

In the vase classes of the amateurs' section the competition was decidedly better than at some previous shows of the Society, and the high quality of many of the exhibits has rarely, if ever, been surpassed. Lady Emsley Carr was first in the class for novelties distributed by Messrs. Stuart Low and Co., and Mr. W. Holder, New Lodge Clinic Gardens, Windsor Forest, was a good second.

There were no fewer than nine exhibits in the class for five blooms in at least three varieties raised by the exhibitor, and the Challenge Cup was won by Lady Gregory (gr. Mr. T. C. Selwyn), Shoreham House, Sevenoaks, with a very creditable collection. Mrs. Walter Burn (gr. Mr. G. H. Wright), North Mymms Park, Hatfield, was first in the class for a decorative vase of not more than twenty-three blooms of Carnations, with a delightful arrangement of superb blooms, and Mr. Henry Atkins, Kingswood Manor Gardens, Tadworth, was an exceedingly good second.

The colour classes also contained particularly good blooms. Mr. Atkins was first with White Pearl, and with Laddie, pink; Mrs. E. M. Walrond (gr. Mr. D. Mitchell), Burton Grange, Cheshire, was first with Mrs. C. W. Ward, medium pink; Master M. Stoop, deep pink; Circe Improved, purple; and Saffron, yellow. Mrs. Burns won first prizes with Topsy, crimson; Circe, violet Fancy; and Red Laddie, red. The last-named variety was of such superb quality as to win the Campbell Amateur Trophy and the Silver-gilt Medal, as well as the first prize in the class which contained many vases of exceptionally high quality.

The Countess of Lisburn (gr. Mr. O. C. Wallon), Cronswood Park, Aberystwyth, also had particularly fine blooms which won the prize offered by Messrs. Allwood Bros. for twenty-four blooms of their novelties, and first prizes in three of the four classes arranged for members who were unable to attend the show. The fourth first prize was won by Mr. W. O. Marshall, Bere Court Gardens, Pangbourne, with a good vase of Topsy.

In the classes for amateurs who do not employ a full-time gardener, Mrs. Kathleen Simpson, Ashton-on-Ribble, was particularly successful in the colour classes, winning first prizes with excellent vases of White Pearl, Laddie, Master M. Stoop, Red Laddie and Topsy.

Decorative Classes.

In the amateur's section, the dinner table decorations were mostly very pretty and attractive in the conventional style of arrangement; Mr. Alfred Swann, Warninglid Gardens, Haywards Heath, was placed first for a rather solid display, with a central arrangement of Spectrum with Croton leaves, grasses and Asparagus plumosus. Mrs. Swann was second, with a table of orange and yellow Fancy Carnations with foliage. Mrs. W. Holder was third with a graceful table of pink Carnations, trails of yellow Selaginella, Asparagus and Grasses; Gus Mayer, Esq. (gr. Mr. R. Cottam), Whistler's Wood, Woldingham, arranged a table which would have pleased most of the visitors a day earlier when all the blooms were quite fresh.

The decorative bowls and baskets were beautifully arranged. Mr. H. Atkins was first with the former, and Mrs. Swann excelled with the latter.

The professional florists dinner table decorations were very bizarre. Mr. W. B. Shearn was placed first, Messrs. Robert Green, Ltd., second, and Messrs. Selfridge and Co., third.

Non-Competitive Exhibits.

Although not numerous, the trade groups of Carnations contributed considerably to the general bright effect, and many grand blooms were shown.

The most spectacular group was that set up by Messrs. C. Engelmann, Ltd. It was tastefully arranged and the blooms were in splendid condition. There were large vases of such splendid sorts as Laddie, very fine; Spectrum, Red Laddie, Ivory, a very attractive white Carnation with frilled petals; and Rouge, very bright. Outstanding among the numerous other sorts displayed in smaller vases were Sceptre, Mrs. C. W. Ward, Gladys, Maine Sunshine, Startler, Topsy, White May Day, Lady Baker, Lady Northcliffe, Mrs. W. Hemus, and Betty Lou.

Messrs. Stuart Low and Co. had in a very charming display, large sheaves of Eileen Low, Melchet Beauty, Philip Sassoon, Topsy, Daphne and Lady Hindlip in the background, with nicely arranged vases of White Pearl, the lovely pink Joyce Low, Thomas Ives, Red Laddie, Spectrum, Laddie, Sunny, Ann Horton, Zorro, the light scarlet R. A. Nicholson, and Mrs. A. J. Cobb, and several others.

In a splendid collection of lovely, clean blooms, Messrs. Allwood Bros. showed Spectrum, Laddie, Wivelsfield Pink, Shot Silk, Allwood's Q. Q., Wivelsfield White, Harmony, Wivelsfield Buttercup, Red Laddie and Topsy, these being the pick of the collection; they also arranged an interesting exhibit of Carnation publications, perfumes, seeds, fertilisers and various implements, etc., necessary to Carnation culture.

Messrs. Keith Luxford and Co. set up a small collection of Carnations, among which White Wonder, Early Rose, Betty Lou and Abundance were notable; they also showed Chrysanthemums.

There were several exhibits of flowers other than Carnations. Orchids were shown by Messrs. Stuart Low and Co.; Cyclamens by Messrs. Blackmore and Langdon; Chrysanthemums by Mr. A. G. Vinten; and Violets by Mr. G. Zambra and Mr. B. Pinney.

Exhibits of sundries included various types of watering-cans, by Messrs. Hawes, Ltd.; and pruning implements by Mr. C. A. Jardine. Miss Alice Baker showed her special metal flower holders, and demonstrated how they should be used by arranging attractive bowls of flowers.

At seven o'clock on the evening of the first day of the show, one hundred members and visitors gathered at the Restaurant Frascati, Oxford Street, for the Annual Dinner of the Society. The evening was a most enjoyable one, and everything went without a hitch; the dinner was excellent, the speeches brief and interesting, and the musical and other forms of entertainment delightful.

The speakers included Lt.-Col. F. R. Durham, Mr. E. T. Willis (President), Mr. J. S. Brunton, Mr. H. Cowley, Mr. L. J. Cook, who proposed the toast to "The Ladies" in very gallant fashion; Mr. Samuel Wallrock, Mr. M. C. Allwood, Mr. C. Engelmann, Mr. R. Campbell and Mr. J. D. Simpson.

Other notable persons present included Mr. David Ingamells, Mr. C. J. Hammond, Mr. George Allwood, Mr. and Mrs. C. J. Miller, Mr. and Mrs. C. S. Bateman, Mr. and Mrs. P. F. Bunyard, Mr. T. Stevenson, Mr. J. Stevenson, Mrs. W. H. Page, Mr. and Mrs. Stuart Monro, Mr. and Mrs. W. Holloway, Mr. A. C. Bartlett, Mr. T. Hay, Mr. A. Bedford, Mr. and Mrs. W. E. Tucker, Mr. and Mrs. W. B. Shearn, Mr. Keith Luxford and Mr. and Mrs. F. W. Alesworth. The press was also well represented.

Mr. Alesworth, the Secretary of the Society, is to be congratulated upon the excellent arrangements which made the dinner so successful.

DUNFERMLINE HORTICULTURAL.

The forty-ninth Annual Chrysanthemum Show of this Society was held in the Drill Hall. There was a large display of cut blooms. The exhibits included fruits and vegetables, and the entries numbered over seven hundred. In the fifteen classes which constituted the open section, the exhibits were notable for their uniformly good quality, and the show, as a whole, was regarded as the best that has yet been held in the Society's history.

The Silver Challenge Trophy for six vases of disbudded Chrysanthemums, not exceeding twelve blooms in each vase, and not more than two vases of one variety, was awarded to Mr. James Lyle, Donibristle Park, who staged blooms of Rufflesque, Madame H. Foureau, Sorcerer, Blanche de Poitou, Cranfordia and Primrose de Poitou, in fine condition. The exhibit gained thirty points, and the vase of Rufflesque was of outstanding merit. Mr. Neil McLean was only half-a-point behind, with quite a good group which consisted of In Memoriam (two), W. H. Thorpe, Cranfordia (two), and Blanche de Poitou. The remaining prize winners in this class were:—Mr. James Mitchell, Broomhall, twenty-eight points; Mr. A. B. Johnstone, Comely Park, twenty-six points; and Mr. John Ralph, Alloa, twenty-five points.

Mr. Lyle was also successful in the classes for six blooms of Japanese Chrysanthemums, with massive examples of Louisa Pockett, one of which measured twenty inches in circumference, and Mrs. B. Carpenter; one vase of Decorative, disbudded flowers (Cranfordia); two vases of Single, disbudded blooms (Catriona and Florrie King); one vase Single, disbudded (Mona); and one vase of any Decorative sort (Rufflesque). This exhibitor's prize-winning record consisted of six firsts, two seconds, and one third.

Mr. John Loan, Coldstream, excelled in the class for twelve blooms, Japanese; his outstanding varieties being Red Majestic, Boule d'Or, Princess Mary and Majestic; he was also placed first for six blooms, distinct varieties. Mr. John Ralph, Alloa, scored with Dawn of Day, Yellow Majestic and Mrs. A. Davis, in the class for three blooms, Japanese and the remaining first prize awards in this section were won by Mr. James Summers, Halbeath, Mr. Neil McLean, Mr. A. B. Johnstone, Mr. R. Haldane and Mr. John Ralph.

The special prize for the best vase of Chrysanthemums in the show was awarded to Swardeston White, which was staged in the amateur and allotment holders' section by Mr. Robert L. Morris, Townhill, and was included in his quartette of Decorative disbudded varieties, not exceeding nine blooms in each vase, which won the Silver Challenge Trophy. These particular white flowers were perfect in form and size, and were the subjects of praiseworthy comment. Mr. J. Bower, Mr. James Summers, Mr. W. Hynd, Mr. D. Robertson (one vase), and Mr. J. Wilson were other prize-winners.

The open Decorative classes were well filled and made a pretty display. Miss Burke provided the best table decoration, consisting of lightly arranged sprays of Source d'Or. Mr. J. Mitchell excelled in the classes for the best bowl and basket: Mr. D. Wilson led in the amateurs' competition for a basket of Chrysanthemums, and the first prize for the bouquet went to Miss Kemp.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the R.H.S. Hall on Monday, November 11, Mr. Charles H. Curtis presiding.

One new member was elected. The sum of £70 4s. 6d. was passed for payment to the nominees of two deceased members. The sick pay for the month on the private side came to £69 8s. 10d., and in the State section, £74 4s. 2d.; Maternity benefits totalled £6. The Trustees reported that they invested £1,000 in five per cent. Conversion Loan. The sum of £51 9s. 6d. was passed in grants to twelve State-insured members towards their dental and optical treatment, and eighteen other cases were considered.

FINCHLEY CHRYSANTHEMUM.

The splendid exhibition of this Society proved most conclusively that even in its forty-fourth year it well maintains its high position in the Chrysanthemum world. The King Edward Hall at Church End, Finchley, London, N., was well filled with a beautiful series of exhibits, in which all types of the Chrysanthemum were exhibited.

Mr. G. Brett, gardener to James C. Jay, Esq., Ganwick, Barnet, again won the Edith Wildash Loving Cup for four vases of specimen Japanese blooms, distinct, three blooms of one variety in each vase, showing well-finished blooms of Mrs. Algernon Davis, Cissie Brunton, Mrs. B. Carpenter and Mrs. R. C. Pulling. Mr. G. H. Kemp, gardener to C. Malpas, Esq., was second.

In the class open to amateur growers, for two vases of Japanese blooms, distinct, three blooms in each, Mr. B. Carpenter, 58, Elm Park Road, N.3 was a good first showing splendid blooms of Majestic, Mrs. A. Holden, Charles Davis, Victory, W. Rigby and Mrs. B. Carpenter; second, Mr. S. W. Cook, South Tottenham. In the same division, for a vase of five blooms, Mr. B. Carpenter was again a good first, showing splendid examples of Victory, Charles Davis, Mrs. A. Holden and Miss Ada Ellis.

In the open division, for two vases of Single Chrysanthemums, the display was one of the best in the show; the competition was good and the blooms superb. The first prize and the National Chrysanthemum Society's Certificate were easily won by Mrs. H. Lawrence (gr. Mr. A. Pettengell), Kirklands, New Barnet; J. J. Ward, Esq. (gr. Mr. E. Edwards), Rocklands, N.3, was second.

Another good competition was the class for two vases of Decorative Chrysanthemums. The first prize was well won by S. Pulham, Esq. (gr. Mr. C. Wright), Finchley, N., followed by Mrs. H. Lawrence, who had beautiful blooms, but much too crowded. For a single vase of Decorative Chrysanthemums, there was again a splendid series, and the first prize was awarded to F. Bastable, junr., Esq. (gr. Mr. A. Cannon).

In the amateur section, for one vase of six Decorative Chrysanthemums, Mr. F. J. King, High Road, Finchley, N.12, won the first prize with a dainty display. Mr. A. Cramphorn was second. A class of exceptional interest was that for a representation of three sections, the winner of the first prize and the Fisher Silver Challenge Cup being Mr. G. Brett, who staged superb Japanese blooms, large, and beautifully finished Singles, and well-grown Decoratives.

Very interesting was the class for one vase of Anemone or Anemone-centred Singles, the first place being easily secured by Mrs. H. Lawrence, who showed lovely examples of Thora, Bronze Thora and Ceres.

The Pompon classes were well filled. For one vase of Pompons, any variety or varieties, Mr. A. Cramphorn was a good first; while in the class for one vase of small Pompons arranged with autumn foliage, Mr. Brett was first with well-grown examples of Baby Doll and a spray or two of Bright Eyes.

The first prize for a bowl of Chrysanthemums was well won by Mr. A. H. Carter, New Southgate, N., the second prize being awarded to Mrs. H. L. Burke; while for the most gracefully arranged basket of Chrysanthemums, with any autumn foliage, a superb exhibit easily gained the first prize for Mr. Alfred Jarvis, Finchley, N.; second, Mr. E. Edwards.

There were many other classes of interest, mostly well filled, including classes for fruits and vegetables.

ROYAL HORTICULTURAL.

The following awards have been made to the undermentioned flowers and vegetables by the Council of the Royal Horticultural Society, after trial at Wisley.

Dahlias.

Class 1. Single.

Award of Merit.

(7) *Red Riding Hood*, sent by Messrs. Van Tubergen.

Highly Commended.

(209) Mrs. Bealey, sent by Messrs. J. Cheal and Sons, Ltd.

Class 2. Mignon Single.

Award of Merit.

(247) *Mrs. William Clarke*, sent by Mr. H. Woolman.

Class 3. Collerette.

Award of Merit.

(18) *Erika*, sent by Messrs. W. Treseder.

Class 6. Small-flowered Paeony.

Awards of Merit.

(35) *Cora*, sent by Mr. C. Turner, and (40) *Dorret*, sent by Messrs. J. Burrell.

Highly Commended.

(31) Mrs. A. F. Dulton, sent by Mr. A. J. Cobb; (54) Jane, by Messrs. J. Burrell; (58) Yvonne Salmon, by Mr. A. J. Cobb, and (65) Tanglewood, sent by Messrs. W. Treseder.

Class 8. Decorative.

Awards of Merit.

(85) *White King*, sent by Messrs. Ballego; (197) *R. Treat*, by General McRae; (217) *Pride of Crawley*, by Messrs. J. Cheal and Sons, Ltd.; (222) *Premier*, (224) *Mrs. John Crowther*, (228) *Fantasy*, and (231) *R. Findlay*, all sent by Messrs. James Stredwick and Son; and (115) *Miss G. Kenkeel*, sent by Messrs. Majoor.

Highly Commended.

(94) Marcehenschon, sent by Messrs. M. Cablee; (113) Ludwig Thoma, by Messrs. R. van der Schoot; (226) Lady Snagge, by Messrs. J.

Cheal and Sons, and (230) Rev. S. Marriott, sent by Messrs. James Stredwick and Son.

Class 9. Small-flowered Decorative.

Awards of Merit.

(126) *Onah*, and (134) *Baldre*, sent by Messrs. J. Burrell.

Highly Commended.

(127) Stella, sent by Messrs. J. Burrell.

Class 14. Star.

Highly Commended.

(162) Hookwood Star, and (213) Rubin, sent by Messrs. J. Cheal and Sons.

Class 15. Cactus.

Award of Merit.

(178) *Early Yellow*, sent by Messrs. Bruidegom.

Highly Commended.

(172) White Wonder, sent by Messrs. Weyers.

Annual Asters.

Awards of Merit.

(170) *Madame Rivoire*, sent by Messrs. Rivoire; (184) *Giant Comet Mauve Queen*, by Messrs. Dobbie and Co., Ltd.; (305) *Mammoth Cinnabar Carmine*, by Mr. Ernst Benary, and (384, 385 and 386) *Ball's White*, sent by Messrs. Nutting, Messrs. John Bodger and Sons Co., and the W. Atlee Burpee Company.

Highly Commended.

(2) Sun-Ball Flesh, sent by Mr. F. C. Heinemann; (7) Triumph Brilliant Rose, by Messrs. Barr and Sons; (13) Lilliput White, and (15) Lilliput White with Red Centre, by Mr. Ernst Benary; (16, 17 and 18) Lilliput Rose, by Messrs. Daehnfeldt and Jensen, Messrs. Watkins and Simpson, and Mr. Ernst Benary; (21) Lilliput Dark Crimson, by Messrs. Watkins and Simpson; (23 and 24), Lilliput Dark Blue, by Messrs. Watkins and Simpson, and Messrs. Daehnfeldt and Jensen; (28) Dwarf Victoria Rose, by Messrs. Dobbie and Co., Ltd.; (36 and 37) Mignon White, sent by Mr. Ernst Benary and Messrs. R. Veitch; (54) Queen of the Market White, by Messrs. John Bodger and Sons Co. (62, 63 and 64), Queen of the Market Bright Rose, by Messrs. John Bodger and Sons Co.; Messrs. Watkins and Simpson, and the Waller-Franklin Seed Company; (74 and 75) Queen of the Market Dark Blue, by Messrs. Daehnfeldt and Jensen, and Messrs. John Bodger, and Sons Co., and (76 and 77) Queen of the Market Purple, by the Waller-Franklin Seed Company, and Messrs. J. Bodger and Sons Co. (alike); (91) Royal Rose, by Messrs. W. Atlee Burpee Company, and (92) Peerless Branching Deep Rose, by Messrs. Clucas (alike); (106) Early Beauty Rose, by Messrs. John Bodger and Sons Co.; (125) King Pink and (129) King Crimson, by the W. Atlee Burpee Company; (133) King Lavender, by the Waller Franklin Seed Company; (140) Giant Comet The Bride, (158) Giant Comet Peach Blossom and (168) Giant Comet Rose, by Messrs. Dobbie and Co., Ltd.; (173) Giant Comet Cinnabar Red, by Mr. Alfred Dawkins; (191) Californian Giant Light Blue, by the W. Atlee Burpee Company; (192) Giant Comet Light Blue, by Messrs. Dobbie and Co., Ltd.; (220) Giants of California Deep Rose, by Messrs. Watkins and Simpson; (229) California Giants Light Blue, by Messrs. Dobbie and Co., Ltd.; (232 and 233) Californian Giants Light Purple, by Messrs. Dobbie and Co., Ltd., and Messrs. John Bodger and Sons Co.; (241 and 242) Ostrich Plume Show Queen, by Messrs. W. H. Simpson and Messrs. Watkins and Simpson, (243) Ostrich Feather White, by Messrs. Daehnfeldt and Jensen, (244) Mammoth Ostrich Plume White, by Messrs. Clucas, and (245 and 246) Ostrich Plume White, by Messrs. Clucas and Messrs. Middlehursts (all alike); (257) Ostrich Plume Rose-pink, by Messrs. W. H. Simpson; (271) Ostrich Plume Terra-cotta, by Messrs. James Carter and Co.; (280) Hercules Rosy Lilac, by Mr. F. C. Heinemann; (288) Ostrich Feather Light Blue, by Messrs. Dobbie and Co., Ltd.; (301) Mammoth White, by Mr. Ernst Benary; (310) Giant Victoria White, by Messrs. W. H. Simpson, and (312) Victoria White), by Mr. Ernst Benary (alike); (325) All Saints Light Blue, by Messrs. Morris; (334) Dwarf Chrysanthemum White, by Mr. Ernst Benary; (348) Astermum Lavender, by Messrs. John Bodger and Sons Co.; (356) Paeony-flowered Perfection Fiery Scarlet, by Mr. Ernst Benary; (359) Paeony-flowered Crimson, by Messrs. Dobbie and Co., Ltd.; (362) Paeony-flowered Perfection Light Blue, by Mr. Ernst Benary; (376) Late Beauty Lavender, by Messrs. John Bodger and Sons Co.; (377) Late Beauty Azure Fairy, by Messrs. John Bodger and Sons Co., (378) Late Beauty Azure Fairy, by Messrs. Dobbie and Co., Ltd., (427) Late Branching Azure Fairy, by Messrs. Watkins and Simpson, (428) American Branching Lavender, by the W. Atlee Burpee Company, (429) Late Branching Lavender, by the Waller-Franklin Seed Company, and (430) American Branching Azure Blue, by the W. Atlee Burpee, Company (all alike); (396 and 397) Peerless Pink, by the W. Atlee Burpee Company, and the Waller-Franklin Seed Company; (398) American Branching Mary Semple, by the W. Atlee Burpee Company; and (403) Tall Branching Shell Pink, by Messrs. Dobbie and Co., Ltd. (alike); (399) Royal Shell Pink, by Messrs. Nutting; (408) Tall Branching Rose, by Messrs. Dobbie and Co., Ltd., and (409) Late Branching Deep Rose, by the Waller-Franklin Seed Company (alike); (419) Crimson Beauty, by Messrs. Clucas; (424) Tall Branching Lavender Pink, by Messrs. Dobbie and Co., Ltd.; (426) Lavender Gem, by Messrs. John Bodger and Sons, Co. (432) American Branching Dark Blue, by the W. Atlee Burpee Company, and (433) Tall Branching Dark Blue, by Messrs. Dobbie and Co., Ltd. (alike); (440) Mikado White, by Messrs. R. H. Bath, Ltd.; (444) Pride of the West, by Messrs. James Kelway; (502) Sunshine Light Blue, by Messrs. R. Blossfeld; (520) Single Pink, by Messrs. Barr and Sons; (530) Single Violet, by Messrs. Barr and Sons, and (531) Sinensis Violet, by Messrs. Hurst (alike); (534) Peerless Yellow, and (535) Salmon Queen, by Messrs. John Bodger and Sons Co.

Antirrhinum.

Award of Merit.

C. H. Herbert, sent by Messrs. W. H. Simpson.

Scarlet Runner Bean.

Award of Merit.

Tip Top, sent by Mr. A. Mitchelson.

DERBYSHIRE HORTICULTURAL.

Mr. A. Roebuck, Adviser in Entomology to the Midland Agricultural College, gave a popular lecture to the members of the Derbyshire Horticultural Association, in the Guild Hall, Derby, on the subject of "Insect Life in the Garden," illustrated by seventy lantern slides, many of them being in colour.

The lecturer showed how the observant gardener could get much entertainment by watching many harmless insects. He began with the primative Compodea, the springtails, the habits of the earwigs, and the harmless psocid. The puzzling capsids were mentioned and various species of aphides. These last are so abundant and prolific that they provide a food supply for many different insects, such as the pretty lacewing hover flies and ladybirds. The problems of parasitism and hypoparasitism were dealt with in connection with the Cabbage white butterfly. The great variety of Lepidoptera was illustrated by the unusual but ever popular hawk moths, the clearwings, the winter moth with its wingless females, the lackey moth, with its caterpillar tents, the twig caterpillars and the pistol-case bearers. Further, the natural and artificial production of varieties was illustrated by the tiger and the magpie moths. Many beetles and weevils were shown; the ever present click-beetles, Apple-blossom and Raspberry weevils, Turnip fleas and burying and rove beetles. In addition, the work of the Clytus larvae in shortening the life of Pea sticks and Bean poles was mentioned. After dealing with some of the sawflies and many of our principal fly pests, a survey of a few species of Hymenoptera was made. The usefulness of the wasps in the early part of the season, the ways of the humble bees, the interesting ways of the leaf-cutter; and finally, the beautiful red lawn bees, so acceptable in the early spring days, were all referred to.

Mr. L. Smith presided, and thanks were tendered to Mr. A. Roebuck by Mr. Wardman and Mr. Seymour.

ROYAL CALEDONIAN HORTICULTURAL.

The exhibits staged at the monthly meeting of the Royal Caledonian Horticultural Society, held at Edinburgh on November 6, were exceptionally numerous and varied in character.

In the competitive section for two vases of Chrysanthemums, Mr. R. B. White, Murrayfield, secured the premier position with five examples of Red Majestic and Mrs. Harold Wells, while Mr. F. Glass, Murrayfield, was runner-up. The vase of H. W. Thorpe, grown by Mr. W. G. Stott, Murrayfield, was awarded first prize in the class for Decorative Chrysanthemums; Mr. J. C. Dempster gained second place.

Competition was keen in the class for six Potatos, and the awards were as follows:—First, Mr. W. G. Pursell, Portabello (Arran Banner); second, Mr. R. B. White (Red King).

The outstanding exhibit in the non-competitive section was a beautiful group of Begonias, which was notable for the colour of the flowers and the floriferous character of the plants. It was staged by the City Parks Department, and included well-grown specimens of the varieties Optima, Exquisite, Elatior, Orange King, Dazzler, Pink Perfection, Scarlet Beauty and Conquest. The Committee recognised the merit of the exhibit by awarding it a Gold Medal. A vase of large, clean, cut blooms, of Lilium auratum var. platyphyllum, grown out-of-doors, was exhibited by Mr. David Armstrong, Drum Gardens, Gilmerton, and Mr. W. Maitland, Murrayfield, showed a pink sport from the Chrysanthemum Parson's White. Other Chrysanthemum exhibits consisted of White Ball, by Mr. William Swan, West House; Mrs. G. Monro and Mrs. H. Wells, by Mr. James Weir, 4, Church Hill Place, and In Memoriam and Blanche de Poitou, by Mr. R. B. White. Miss Burton, New Saughtonhall, Polton, showed a dish of Arran Banner Potatos.

Mr. Jeffrey presided over a large company which was entertained by the Rev. D. C. Stewart, of Currie, who lectured on "Scottish Humour."

CARDIFF GARDENERS'.

At the meeting held at the Queen's Hotel, Cardiff, early in November, Mr. W. H. Pryce presided. The meeting was well attended by many gardeners, who were all anxious to hear the lecture on "Strawberry Diseases," given by Mr. L. N. Staniland, of the Horticultural Research Station, Long Ashton, Bristol. This proved a very interesting lecture to all, and much useful knowledge was gleaned from the lecturer's remarks on various Strawberry troubles, which included red leaf, cauliflower and patch diseases, and also the Strawberry aphis. All these were described and illustrated, and from the observations made at Long Ashton, it was stated that there is every probability of stamping out these various diseases of the Strawberry that have been so prominent and destructive in private and market gardens during the past ten or twelve years. The lecturer emphasised the importance of obtaining clean stock to commence with, and the care in selecting runners, which should never be taken from plants carrying fruits.

A long and interesting discussion took place and many questions were asked by members and ably answered by Mr. Staniland, who, at the close, received a hearty vote of thanks.

Prizes were offered for the best blooms of Japanese Chrysanthemums, and the first prize was awarded to Mr. W. W. Crouch, and the second to Mr. Lidgett Gibbs. For the best nine blooms of Single varieties, Mr. Jones was first, Mr. H. Jenkins second, and Mr. W. W. Crouch third. Points were also awarded to Mr. Baker for Grapes, Mr. Kirby for Apples, and Mr. Pryce for Chrysanthemums

KINGSTON AND SURBITON CHRYSANTHEMUM.

The twenty-second Annual Show of this Society was held on November 6 at Surbiton Assembly Rooms, and proved to be a great success. There were far more entries than usual, and the quality of the flowers was much better than anticipated after the difficult season. The Challenge Cup given by the tradesmen of Kingston and Surbiton was won by Lady Juliet Duff (gr. Mr. H. Weaver), Coombe Court, Kingston, with eighteen Japanese blooms; these were very fine examples and included the grand bloom of Mrs. B. Carpenter which won the National Society's Certificate and a special prize for the best bloom in the show. Mr. Weaver also won the Davis Cup for three Chrysanthemum plants, and many other prizes.

The Hanks Challenge Cup for a group of Chrysanthemum plants in pots was awarded to Mrs. Costain (gr. Mr. J. Pike), Woodlands Park, Leatherhead. This group was well staged and contained some very fine flowers. Mrs. Pike also won the Bond Cup for a group of miscellaneous plants, which was well put up. The Hodgson Challenge Cup was won by H. Becker, Esq. (gr. Mr. Manwaring), Surbiton, with twelve Japanese blooms in distinct varieties; this exhibitor also won the Cup last year. The Wigley Cup, for amateurs, given by the President of the Society, was awarded to Mr. C. Hawkins, of Kingston, who staged a dozen Japanese blooms which closely rivalled those of the professional growers, and included the fine bloom of Mrs. A. Holden which received the National Society's Certificate and a Special Prize as the best bloom in the amateurs' classes.

The Silver Cup offered by Sir G. Penny, M.P., to the lady gaining the most points in the show, was awarded to Mrs. Barrett, of Thames Ditton, for three bottles of preserved fruits in exceptionally good condition. Fruits and vegetables were well-shown both by cottagers and professional gardeners. The first prize for Grapes was won by G. C. Hodgson, Esq. (gr. Mr. Belfield), Surbiton, who staged two fine bunches of Muscat of Alexandria.

AYR CHRYSANTHEMUM.

The twenty-third annual exhibition of this Society was held on November 20, and in respect to entries the number created a new high record. In the cut flower section the increase exceeded fifty, and to provide the necessary accommodation the decorated dinner table classes had to be abandoned. Owing to the representative support given by growers in different parts of the country, the show has assumed something of a national character, and the quality of the exhibits generally reflected a very high standard of production, particularly in the Japanese and specimen plant classes.

There were twenty-nine classes in the gardeners' section, and the championship in the form of the Land of Burns Cup, for four vases of Japanese Chrysanthemums, three blooms in each, was won for the second year in succession by Mr. Hugh McSkimming, gardener to George McLellan, Esq., Auchenault, Helensburgh, with well finished blooms of Dawn of Day, Princess Mary, Mrs. B. Carpenter, Louisa Pockett, R. C. Pulling, Lady Talbot, T. W. Pockett and Queen Mary. The bloom of Lady Talbot was awarded the special prize for the best flower in the show, and Mr. McSkimming was also successful in the classes for three Japanese blooms, white; three yellow, and three blooms of bronze or crimson Japanese Chrysanthemums. The outstanding bloom in the crimson class was Birmingham, a grand variety included in the first prize trio. Mr. McSkimming also provided the best twelve Japanese blooms shown on boards.

On his first appearance as a competitor, Mr. James Hutchinson, Kilmarnock, had a unique experience. He was awarded the Silver Cup in the confined class for twelve Japanese blooms shown on boards, and in the amateurs' section he won the Silver Cup for two vases of Japanese varieties, and a Rose Bowl for six Japanese blooms shown on boards. He also scored in the competition for six new varieties introduced since 1926, with well-grown examples of Aquitania, Mrs. Holden, Mrs. Keith Luxford, Yellow Majestic, Red Majestic and T. W. Pockett. Mr. Watt was second.

The Rose Bowl for three vases of Single Chrysanthemums went to Mr. George McCartney, Orangefield Gardens, Monkton, who also excelled in the classes for pot plants.

The best pot plant in the show, however, was grown by an amateur, Mr. Norman Jamie, who staged a handsome specimen of H. W. Thorpe, carrying eighty-five blooms. His prize-winning record consisted of five first prizes for pot plants, and three for vases. Romance, an Incurved yellow variety, was outstanding in his collection.

Other names prominent in the prize list were Mr. R. J. Clark, Mr. R. Livingstone, Mr. W. Murdock, Mr. G. Kerr and Miss Carnegie.

The non-competitive exhibits consisted of a representative collection of the newer Japanese and Single Chrysanthemums. They included a good collection by Messrs. William Marshall and Co.; a smaller group of high-class blooms from Messrs. Carnegie and Sons; Begonias, by Messrs. Austen and McAslan; alpines, by Messrs. McGill and Smith; and a miscellaneous exhibit of fruits, flowers and vegetables, by Messrs. Learmouth, Hunter and King.

Obituary.

Joseph Evans.—Few gardeners will be more sadly missed than Mr. Joseph Evans, who had spent the past twenty-five years of his life as gardener at Snaprails, Sandhurst, in the employ of W. Napier Church, Esq., by whom he was held in high esteem. His painfully sudden death on Friday evening, the 15th instant, at the comparatively early age of fifty-nine years, came as a great blow to all his friends. His usual routine in the garden was carried out even on the day of his death. Much sympathy is felt for his widow, son and three daughters, and many of his intimate friends in Berkshire and west Surrey were, owing to the early interment, unable to pay their respects by attending his funeral, which took place on the following Monday. Horticultural societies throughout the district will miss the excellent exhibits of plants, flowers and vegetables with which he won many high awards. His activities were by no means confined to gardening, as his position as Chairman of the Sandhurst Working Men's Club will testify, together with his association with the Sandhurst Silver Prize Band, whose reputation is due largely to his efforts. He spent his life in the service of others, and his cheerfulness was an inspiration to all.

H. J. Lemkes.—We regret to learn of the sudden death, at the age of sixty-seven, of the Dutch nurseryman, Mr. H. J. Lemkes, who passed away at Alphen a/d Rijn on November 11. Mr. Lemkes was born in 1862, at Alphen, and early showed considerable taste for horticulture. After several years spent in acquiring varied knowledge, he established while still quite young, a small nursery of his own in his home town, and this gradually developed in size and scope until it became well-known as a source of supply for excellently grown Ferns, Cyclamen, Asparagus foliage, Arums, and latterly, Palms and Azaleas also. The deceased was of a very retiring disposition, but was always ready to do good in an unostentatious way. After his three sons were old enough to take over the main cares of the business, the elder Lemkes retired from active work, but still interested himself in its affairs, while at the same time taking a part in local philanthropic and religious activities. He was very much respected and beloved at Alphen, and will be greatly missed by a large circle of friends.

ANSWERS TO CORRESPONDENTS.

Apple Mrs. Phillimore.—*D. C.* This Apple was raised by Mr. Charles Ross, by crossing the varieties Lord Burghley and Gladstone, and introduced to commerce in 1900. We have no record of it as a market variety, but it is certainly worthy of trial. [Thanks for 2s. 6d. for R.G.O.F. Box.]

Gentiana verna, Oxalis lobata, etc.—*C. E. T.* (1) Gentiana verna grows quite readily from seeds if these are sown in spring on a well-drained compost of loam, leaf-mould, and sand, in a pot placed in a cold frame, care being taken not to sow too deeply. After germination keep the seedlings fairly moist. (2) Oxalis lobata does best when planted along the base of a rock in a sunny position in good, well-drained, gritty soil. O. enneaphylla grows well and flowers profusely in a semi-shaded position on a ledge, planted in well-drained leaf-mould, loam, chips, etc. O. adenophylla flowers well in the rock garden at Kew in rather sunnier and more sheltered positions than the preceding, in good gritty soil. (3) Take cuttings of the Lupin, if possible, after beheading the flowering stem, or divide the crowns in the spring of the second year, and so on. (4) Lithospermum prostratum is best raised from cuttings of half-ripened wood inserted in early autumn and placed in sand in a cold frame. (5) The Erodiums mentioned may be propagated by division in early summer or by cuttings inserted in sand later, or from seeds sown in early spring. (6) Divide the Gentians at the end of March or beginning of April. Gentiana septemfida may be propagated by cuttings taken in early summer and inserted in sand in a cold frame, or raised from seeds sown in spring. (7) Propagate the Gypsophila by taking cuttings of the young wood, with a heel, and inserting them in sand in early summer. A little heat in this case is helpful. Cuttings may also be taken of half-ripened wood, care being taken to ensure the covering of the lower node with sand or compost; if this is difficult owing to the cuttings being too long, sever them at an internode, leaving two nodes on the stem, one above ground and one below, when they are inserted in the propagating case.

Gladiolus Corms Diseased.—*G. J. T.* The Gladiolus corms have been attacked by some soil pest, *e.g.*, slugs or surface caterpillars, the larvae of the Turnip or heart and dart moths. Two of the corms show beneath the outer scales the lesions usually associated with Fusarium disease. Too little is known at present on the control of this and similar diseases of Gladiolus, but sufficient is known to warrant the destruction of all corms showing signs of having been attacked by fungi or bacteria. Diseased corms should not be kept in storage as they will decay and become a source of infection. The treatment of infected land with a two per cent. formalin solution may have a sterilising effect, but rotation should be practised rather than run the risk of planting corms in infected land next year.

Names of Plants.—*G.* Pieris floribunda.—*A. S.* 1, Cotoneaster Simonsii; 2, Cydonia japonica.

Rating Relief.—*J. W. W.* As you have been given an appointment to appear before the Assessment Committee you will have an opportunity of stating your case to this Committee. You should lay stress on the fact that your holding comprises a dwelling-house and that you are primarily engaged in carrying on agricultural operations on the land connected with the house, if such be the case. If the Assessment Committee holds that you are not entitled to have the house assessed at a lower valuation than if it was assessed as a dwelling-house for general use, you should obtain legal advice as to your prospects of success in an appeal to the Quarter Sessions.

Vegetative Propagation. There is no need to emphasise to gardeners the importance of acquiring the utmost skill in the art of propagation; for although some plants lend themselves readily to multiplication by vegetative means, others are not at all easily reproduced by vegetative propagation. Thanks, however, to the fertility of resource of enterprising gardeners, all sorts of ways and means have been discovered which often prove successful in inducing plants unamenable to ordinary methods, to increase and multiply vegetatively. Thus, as everybody knows, there are not a few plants which, although they may not readily strike root from stem cuttings, do so when root cuttings are taken. Of many garden plants which may be propagated in this way Seakale and Anchusa italica are common examples. The property which some plants possess of reproducing themselves from root cuttings has led in certain cases, as, for example, Bouvardia, Pelargonium, Phlox and others, to the discovery that the plant raised from a root cutting may differ in certain respects, as, for example, colour of flowers, from the plant from which the cutting was taken; thus providing an exception to the general rule that vegetative propagation ensures uniformity of type. The curious in these matters will find much to interest and puzzle them in the account of the behaviour of varieties of Pelargonium zonale given on p. 405 of a recent issue of this journal. Nothing is more amazing to the philosophically minded gardener than to discover in beings which are such creatures of habit and convention as are plants, this sudden kicking over the traces and breaking away from tradition which characterises these well-named "sporting" plants. The practical gardener, having been so successful in discovering new ways of inducing plants to propagate themselves, has in turn been followed, and with equal success, by the scientific horticulturist. The exploration of means of inducing vegetative propagation was a subject which interested greatly the late Professor Sir Isaac Bayley Balfour; and no wonder, for no one has combined in himself more harmoniously the scientific and practical, as did he. Thanks, no doubt, to his inspiration, Edinburgh has always been to the fore in this line of investigation. The most recent evidence of this preoccupation with problems of plant propagation are two brief papers in the *Transactions of the Botanical Society of Edinburgh*.[*] In the former of these two contributions an illustrated account is given of the rooting of leaf-cuttings of such unlikely subjects as Ginkgo biloba and Podocarpus macrophylla, and of a verity, were it not for the unimpeachable testimony of the authors, we should have thought that the leathery-leaved Maidenhair Tree would not have proved a successful subject for the operation of taking leaf-cuttings. But with plants, as with life in general, "you never can tell." The list of plants which may be raised from leaf-cuttings is already a long one. Apart from the well-known case of Begonia, leaf-cuttings may be made from Acanthus, Acalypha, Alloplectus, Alsomitra, Brownea, Chirita, Coleus, Dioscorea, Eranthemum, Ficus, Gasteria, Gesneria, Jacobinia, Kopsia, Medinella, Panax, Peperomia, Rosa, Ruellia, Sanchezia, Sansevieria, Vitis and Zamioculcas. Then there are, of course, the plants which themselves apply this method of propagation, species of Begonia, Bryophyllum, Malaxis and Kalanchoe, for example. All of these viviparous plants are interesting, although, perhaps the most interesting is Kalanchoe verticillata, whose leaves, while they are still in an extremely early stage of development, begin to make preparation for the multiplication of the species by forming buds on their horned tips. Some day, these interesting experimental studies will no doubt be carried much further. Some skilful manipulator will succeed in dissecting out the individual cells which give rise to a new bud and, growing them in artificial media, will raise a new and complete plant from such a single cell. In the meantime, those who have leisure might well interest themselves in the useful art of finding out how species which ordinarily propagate with difficulty may be made to reproduce themselves readily; for, as the late Reverend H. J. Bidder, of fragrant memory, used to say to the beginners, when lavishing his garden treasures upon them: "To make a garden you must propagate and propagate and propagate your plants."

The "Gardeners' Chronicle" Almanac for 1930.—The preparation of our Almanac for 1930 is now proceeding, and as we are anxious to include so many dates of horticultural exhibitions and meetings as possible, the secretaries of horticultural, botanical and kindred societies are invited to send us the dates of their fixtures for the coming year, to reach us on or before December 31, 1929.

Chrysanthemums in the Temperate House at Kew.—The spacious dimensions of the Temperate House at Kew and the abundant green foliage of its occupants, form an ideal setting for Chrysanthemum plants, numbers of which are grown as specimens, in most cases three plants in a twelve-inch pot, partially disbudded, and carry from forty to sixty flowers on each specimen. These are arranged on either side of the path through the centre of the house, mostly in groups of four, five or more examples of one variety, but each specimen stands out distinct from its neighbour. Most of the varieties represented belong to the Decorative and Single-flowered sections. Those of outstanding merit include Josephine Bernier, pink, lighter centre; Brilliant, crimson, gold reverse; September Gold, rich yellow; Portia, single, terra-cotta; Godfrey's King, bronze; and the following white varieties: Niveus, Madame R. Oberthur, Mrs. Clibran, Robert Thorpe, single; and Mrs. O'Neil, this last being a most attractive free-flowering Single variety.

Mr. William Cuthbertson's Jubilee.—At a social gathering of the employees and friends of Messrs. Dobbie and Co., Ltd., held at Edinburgh on Thursday, November 28, Professor Daniel Lamont, in the course of an address on the progress of the firm since the headquarters were removed from Rothesay to Edinburgh, mentioned that this was the jubilee year of Mr. Cuthbertson's association with the firm of Dobbie and Co. It was a wonderful achievement to spend fifty years of one's life with one firm, but it was more wonderful when they considered the character of the work, the energy, the initiative and skill applied during half-a-century. He sometimes wondered at Mr. Cuthbertson's great versatility, particularly in the realms of science and art. He recalled a meeting held at Rothesay in 1902 in connection with the firm at which two subjects were to be banned. One was politics and the other was the champion Leek. At the right hand of the Chairman on that occasion sat Mr. James Dobbie, the founder of the business, who had a speech written, but did not deliver it. It was read by Dr. Hewison, and what interested him most was that it combined the two permanent traditions of the firm—energy well directed, and good feelings towards the employees. This old man approved of the new policy of the firm, gave it his blessing, and predicted its success. How that prophecy had been fulfilled was known to them all.

Surplus Potato Crops in Scotland.—How to dispose of the heavy stocks of Potatos that have accumulated this season in Scotland is a problem exercising the minds of growers in different parts of the country. The Executive of the National Farmers' Union has suggested that surplus stocks should be exported to South American and Mediterranean ports, but that proposal was turned down at a meeting of the Perthshire branch on November 29, because of the sacrifice imposed on the growers. Mr. John A. Buchan blamed the British Ministry of Agriculture for talking so much about Wart Disease, which was responsible for the attitude of the United States in placing an embargo on British-grown produce. There was a strong feeling in favour of placing the same restrictions on foreign Potatos as foreign countries had placed on British Potatos. Mr. J. Lennox made the novel suggestion that as Wart Disease emanated mainly from gardens, farmers should combine to prohibit the growing of Potatos in gardens, and, if necessary, give Potatos free to gardeners in compensation. Mr. Hugh McLean put his finger on the weak spot when he stated that farmers had themselves to blame to a great extent because of the stuff they were putting on the market. In Glasgow and the west particularly he had had served up to him Potatos which were hardly fit to eat.

[*] "Vegetative Propagation: Leaf Cuttings in Gymnosperms," by R. J. D. Graham and L. B. Stewart; and "Vegetative Propagation: Kalanchoe verticillata," by C. M. Baron, R. J. D. Graham and L. B. Stewart.

Liege International Horticultural Exhibition, 1930.—Besides the World's Fair and International Horticultural Exhibition, to be held at Antwerp during the spring and summer of 1930, there is to be a large exhibition at Liége during the same period, in the beautiful fifteen-hectare park on the banks of the Meuse. It is intended that the agricultural and horticultural section of the exhibition shall comprise a model village, which will serve to demonstrate the progress achieved in the various phases and processes concerned. A large and up-to-date farm will illustrate the use of electricity in rural districts, a second farm will show the latest agricultural machinery, a cottage with a garden and orchard will show what can be done with a small allotment, and other exhibits will be a modern poultry-farm, a bee-farm, a village restaurant, and a display by the Government Department of Waters and Forests.

Dutch Auction at Antibes.—A machine for the holding of silent auctions in the flower trade has been established at Antibes, this being the first to be used in France. The machine has been imported from Holland, and is worked by electricity, as is the dial used in the well-known sales at Aalsmeer. The cost is being defrayed jointly by the flower-growers and exporters of Antibes, Cagnes, St.-Laurent-du-Var, Beaulieu and other centres in the south of France.

Afforestation and the Rabbit Menace.—It was noted in these columns at the time the Scottish Forestry Commissioners took over the estate of Burghead, Morayshire, a large part of which is covered with blown sand, that there was "one fly in the ointment—the rabbit menace." Some idea of the gravity of the menace may be imagined when it is stated that those controlling the warrens expect to send over 5,000 rabbit pelts to the fur merchants during the next four months, and to that there must be added 4,000 already killed this season. The toll these creatures take of newly planted areas is a heartbreak to the forester. It is hoped, however, the strenuous efforts now made to combat the pest will ultimately prevail. After an area has been prepared for planting, it is carefully wired off and rendered rabbit-proof. But should a gate be left open, the entry into the forbidden and cleared areas by two or three bunnies very soon tells a tale. The astonishing prolificacy of the creatures very soon founds a colony. But the work of afforestation proceeds apace. Already over eighty acres have been planted with 165,000 Corsican and Scots Pines, and are all doing remarkably well. During the planting season, which started the other day, those in charge hope, given anything like favourable weather, to afforest another 15,000 acres. The fine experience gained in afforesting the Culbin Sands, a herculean task directed by Mr. Annand, the Forestry Officer in the north-eastern districts of Scotland, is playing an invaluable part in the work at Burghead. The objective in both the areas is the same—to prevent the drifting sand from overwhelming many acres of the finest agricultural land in Morayshire.

Export of Belgian Plants to Spain.—M. Charles Pynaert, the well-known Belgian horticulturist, has just visited Spain with the object of obtaining some modification of the regulations which have lately been made in that country for the importation of plants. He has been able to secure that foliage plants (Kentias, Palms in general, Dracaenas, Araucarias and Laurels) shall be admitted to Spain in complete waggon-loads, provided the permission of the Spanish Government has been obtained, and that the soil attached to the roots or in the pots be completely removed and replaced by Spanish soil. So far as Azaleas are concerned, negotiations are still proceeding, but it is hoped to arrive at a satisfactory decision.

"Hardy and Half-hardy Plants."—In the issue of *Hardy and Half-hardy Plants* for November, Mr. A. W. Darnell gives excellent illustrations and brief descriptions and cultural notes of Codonopsis ovata (coloured); Tricuspidaria dependens (syn. Crinodendron Hookerianum), a striking crimson-flowered, half-hardy shrub from Chile; Sternbergia Fischeriana, Aristea corymbosa (syn. Witsenia corymbosa), the Tree Iris; Primula viscosa, Ambrosinia Bassii, the Pixy Arum; Veronica macrantha, a large, pure white-flowered species; Chiliotrichum diffusum, an attractive shrubby Composite from the Falkland Islands; Bomarea acutifolia, Pogonia ophioglossoides, the dainty Adder's-tongue Orchid of North America; Convolvulus althaeoides, Hydrolea spinosa, Colchicum umbrosum, Primula minima, Menziesia ciliicalyx, Lilium sutchuenense, Oxytropis bella, not yet in cultivation, but stated as likely to prove welcome on the rock garden; Shortia galacifolia, Aristolochia Clematis, Rhododendron lapponicum, and Trichomanes reniforme, the New Zealand Kidney Fern.

Mr. H. B. Witty.—On November 11 the official career of Mr. H. B. Witty as Superintendent of Parks, Cemeteries and Recreation Grounds to the Hull Corporation, came to an honourable close, as he then retired on superannuation, after having served the Corporation for forty-one years. Mr. H. B. Witty was born at Cottingham in the year 1864, where his father was a nurseryman and seedsman, and his early years were spent in association with this business. He received a thorough training in every branch of the nursery and seed business, and this excellent grounding served him in later years. As a young man he went to Kew, leaving the Royal Botanic Gardens at the end of two years and three months. The call of his native district was so insistent that he returned to Hull and commenced business on his own account. This he conducted until 1888, when he was appointed Superintendent at Western Cemetery. The appointment took effect before the cemetery was officially opened, and it fell to Mr. Witty to complete the lay-out of the site, which he supervised until 1901. In that year he was appointed Superintendent of Parks and Cemeteries in succession to the late Mr. E. A. Peake. During the past twenty-eight years, the Parks and Cemeteries Department at Hull has grown amazingly, and it is now among the most modern in the country. This transformation is largely due to the untiring efforts of Mr. Witty. In no city in the kingdom of comparable size are there more street trees, and no fewer than twenty men are continuously employed in keeping these in order. There are four large parks in which the best features of horticulture are well represented, together with every facility for music and games. Several disused burial grounds exist in the city, and these have been brightened with flower-beds and converted into havens of rest for the general public. More than three thousand allotments are included within the purview of the department. All these sections have received the personal attention of Mr. Witty, who has assisted their development in every possible way. In the last few months before his retirement, he took an active part in the formation of a new golf course and park at Willoughby, which it is hoped will be ready for use next Easter. There are three large cemeteries in the city, and a fourth is in course of formation. Mr. Witty has for twenty-five years displayed a keen interest in the welfare of the Hull and East Riding Chrysanthemum Society, having served on the Committee for that period, and the present prosperity of the Society is in no small measure due to the practical interest which Mr. Witty has shown in it. The Hull Parks and Burial Committee, at the last meeting which Mr. Witty attended prior to his retirement, decided unanimously to present him with an illuminated address, inscribed on vellum, as a recognition of the valuable services which he has rendered to Hull. We wish Mr. Witty much happiness in his well-earned retirement. He is succeeded by Mr. G. H. Copley, N.D.H., who goes to Hull from a similar position at Dewsbury.

MR. H. B. WITTY.

Legacies to Gardeners.—Miss Sophia Mary Arkwright, of Nutwood, Grange-over-Sands, Lancashire, who died on August 24, left £100 to Mr. Joseph Steem, gardener, if still in her employ.—Colonel Sir John Arthur Anstice, K.C.B., of The Old Grange, Dymock, Gloucester, who died on August 1, 1929, left £50 to his gardener, Mr. Joseph Trotter.

National Park and Sanctuary for Flowers and Animals for Scotland.—The project of a national park and sanctuary for the preservation of what remains of the flora and fauna of Scotland is slowly but surely making progress in the public mind of Scotland, and it is beginning to be realised that if nothing is done in this direction soon it is quite conceivable that in a few years hence there may be little left of the natural beauties of the countryside. The erection of factories, opening of new mines, quarries, and the draining of lochs and the utilisation of water falls, are all having an adverse effect on "Bonnie Scotland." It is felt, too, that should the project adumbrated be properly gone into, the area must be large and representative in character not only of typical Scottish scenery, but also of animal and plant life. Canada and America have had national parks and sanctuaries for years, but the scale suggested for Scotland is humble in the extreme compared with these gigantic areas. Two sites are meantime before the projectors—the Island of Arran in the Firth of Clyde and the Cairngorm mountain range. What militates against Arran is its position and the fact that during the summer season it is overrun by Glaswegians and other holiday-makers. But the Cairngorms, perhaps the finest mountain range in the British Isles, would make an ideal national park and sanctuary. As a start it is suggested that Glenmore, a large estate in the Cairngorms, should be acquired for the nation. It is an area of great beauty and also of great interest, extending as it does to the summit of Cairngorm, over 4,000 feet in height. The principal summits, each over 4,000 feet, are Ben Macdhui, Braeriach, Cairntoul and Cairngorm, and not far off the 4,000 feet level are Ben Avon and Ben A'Bhuird. Glenmore forms only a small part of the region which is known as the Cairngorms, but within it are magnificent corries, glens and lochs, noble forests of ancient Pines adding greatly to the beauty and majesty of the area. The Scottish Forestry Commissioners, who own 12,500 acres of the Cairngorms, including the mountain itself which gives the range its name, and Loch Morlich, have expressed their willingness, on conditions, to transfer their rights to the Scottish Forest Reserve Committee. Of the acreage given 8,500 acres have yet to be planted. There is no intention of making the Cairngorms into a glorified tea garden, their isolation forming really one of the advantages of the scheme. It would be desirable, however, that reasonable access be given to the outskirts of the region, leaving the true lovers of nature who walk miles and at times risk their lives, to enjoy the solitude and majesty of the everlasting hills. Hence it is not suggested that the majesty of the region should be spoiled by the indiscriminate construction of roads and paths and hotels.

As it is, the suggestion to make the Cairngorms into a National Park is adversely criticised by enthusiastic mountaineers. They ask—How many of, say, the mining population of Scotland would care to avail themselves of the chance of climbing any of the high Cairngorms? Are the quiet recesses of the Grampians to be opened up by means of roads, public houses and other plebeian inducements on the off-chance of getting charabancs and their usually noisy crowds scattered over these sacred places? The result of that would be that those who really love the mountains would be driven away from them. The charm of those places would be lost on account of the litter and the din that would almost inevitably follow the trail of such excursionists. It has to be remembered that the general public must be educated to respect these beautiful spots. Indeed, lack of the training of the multitude to respect such places has been the cause of the exclusion of the few who would value highly the privilege of having free access to them. But as Lord Bledisloe, who is an enthusiast for the preservation of England's beauty spots, puts it—"We have grown so used to regarding the 'tripper' as a vandal that we cannot imagine conditions under which such people, instead of wanting to destroy or maim wild life, will as a matter of honour and national duty feel themselves bound to protect it. Yet this has been the experience of the Transatlantic park authorities." Encouraging, certainly. The flora of the region under review makes up a wonderful collection, while the fauna includes many wild creatures now nearly extinct in these islands. There is the eagle, the wild polecat, the curlew, whose eerie cry of warning of impending danger to its fellow creatures around it is the bane of the sportsmen, and a host of others who meantime find sanctuary in the Cairngorms. These would all be preserved. Concerning the proprietors of the proposed park, the largest is H.R.H. the Princess Royal, widow of the late Duke of Fife, who owns the Mar Forest; Glen Avon is the property of the Duke of Richmond and Gordon, while part of Ben A'Bhuird and Ben Avon are the Invercauld property of Lt.-Col. A. H. Farquharson. Rothiemurchus and Glen Einich belong to Mr. Grant of Rothiemurchus, while Glenfeshire is the property of Sir George Macpherson-Grant, Bart., of Ballindalloch. Rising thus at the extreme end of Aberdeenshire, on the borders of Perthshire, the proposed park would end in Banffshire.

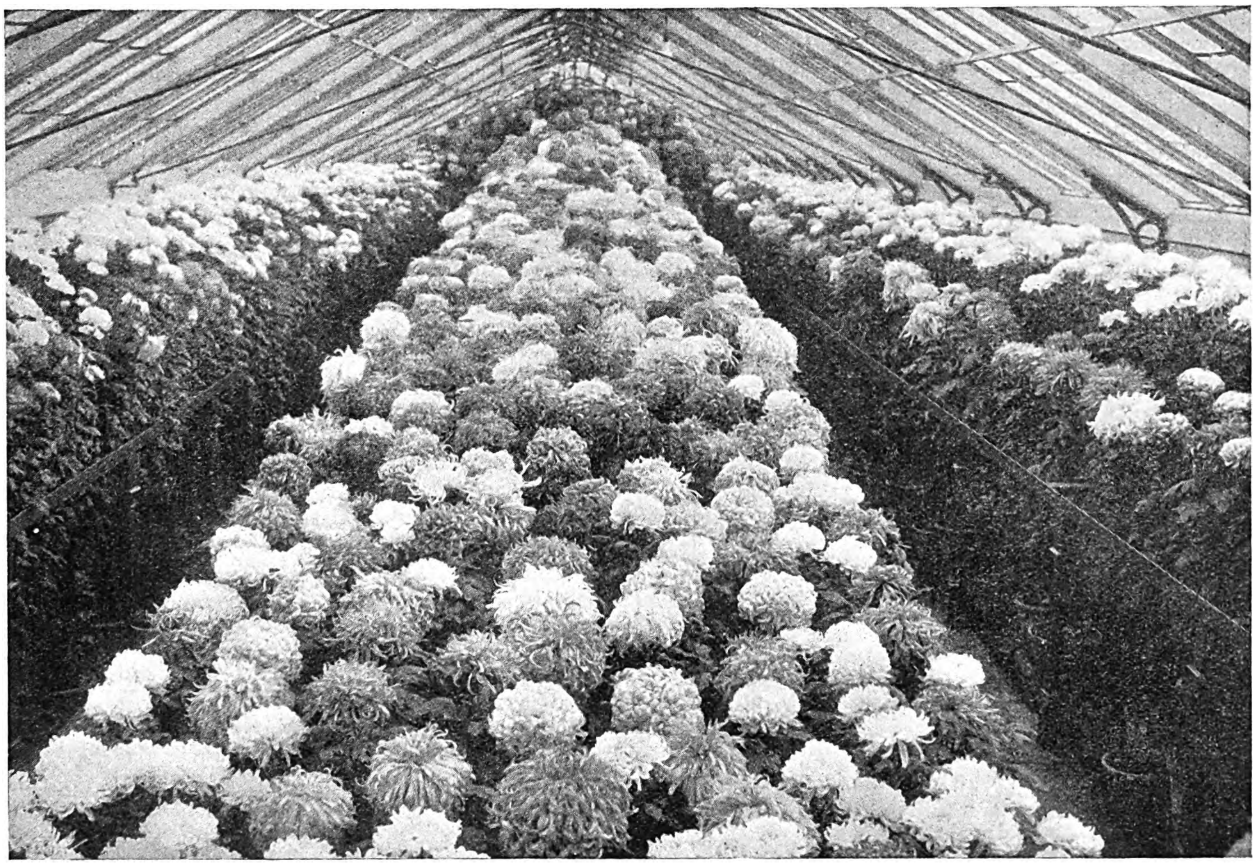

FIG. 202.—CHRYSANTHEMUMS AT OAK HILL PARK, ACCRINGTON.

Chrysanthemums at Oak Hill Park, Accrington.—In almost all large centres of population it is the custom for the Parks Department to produce an autumn display of Chrysanthemums, provided there is a suitable glass structure in which to house the plants. The popularity of such displays is beyond all question, as the attraction of beauty in form and colour is the same in all parts of our islands. We cannot possibly reproduce all the photographs of public Chrysanthemum Shows we receive, but we have pleasure in illustrating the display provided in Oak Hill Park, Accrington, by Mr. H. Boyd, the Parks Superintendent of that borough. Before the end of November no fewer than nine thousand people passed through the greenhouses and admired the Chrysanthemums. The central grouping consisted of exhibition blooms of such fine varieties as Birmingham, Mrs. M. Sargent, Leicester, Charles Davis, Thalia, Aloma, Mrs. G. H. Pearce, Mrs. F. C. Maples, Mrs. Keith Luxford, Superb, Lady Findlay, Aquitania, Miss Ada Ellis and Lady Miller. The white variety along the sides of the house is Blanche de Poitou, and in front of this a collection of the best Single and Decorative varieties was arranged.

Celery-growing in the Isle of Axholme.—Celery-growing is becoming an important industry in Cambridgeshire and Lincolnshire, especially in the Isle of Axholme, which forms the northern corner of the latter county and covers an area of about 50,000 acres. An account of the Celery-growing industry in the Isle is given very thoroughly by Mr. Arthur Jones and Mr. S. M. Makings, in a booklet entitled, *Celery Production in the Isle of Axholme*, published by the Midland Agricultural College, Sutton Bonington, Loughborough, price 1s.

Appointments for the Ensuing Week.—MONDAY, DECEMBER 9: Birmingham and Midland Counties Gardeners' Association's lecture. TUESDAY, DECEMBER 10: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting. WEDNESDAY, DECEMBER 11: Wimbledon Gardeners' Society's meeting: Sheffield Chrysanthemum Society's lecture. FRIDAY, DECEMBER 13: Royal Horticultural and Arboricultural Society of Ireland's meeting. SATURDAY, DECEMBER 14: Leeds Paxton Society's Vegetable Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Sir Joseph Paxton.*—Sir Joseph Paxton has now received, through the electors of Coventry, the highest honour which his countrymen have it in their power to bestow. And he has well deserved it. From a very humble station he has risen by a rare combination of industry, talent, enterprise and integrity, to the highly honourable post conferred upon him. Long may he live to fill it with credit to himself and advantage to his country. We are precluded by our compact with the public from engaging in party politics. Even in the absence of such a compact we should avoid them. We may, however, venture to say, what we know that the great middle class of English will heartily re-echo, that such men are much wanted in the House of Commons, independent, honest, fearless, not to be intimidated by mob violence, not to be deluded by sentimental folly, not to be cajoled by Treasury blandishment. What his politics may be is in our eyes immaterial; good men and true are to be found on every side of the House of Commons. But this we may say of Sir Joseph Paxton, whom we have known for many a long year, that he is a thoroughly upright as well as a clever man, and of the true stuff of which recruits for Parliament should be made. *Gard. Chron., December* 9, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Hybrid Epidendrums.—Hybrids of the E. Endresio Wallisii type thrive well when grown in the intermediate house, and are now producing roots freely in conjunction with the robust young growths. The plants should be well supplied with moisture at the roots each time the compost approaches dryness. These Epidendrums should make a grand display of flowers for many weeks during the late spring months. The plants should be examined frequently for the presence of small scale insects, which are generally to be found in the axils and on the undersides of the leaves; these should be removed by careful sponging and a small, pointed stick, so soon as detected.

Tall-growing Epidendrums—Such species as E. radicans, E. O'Brienianum, E. xanthinum, E. Boundii, etc., which produce long, Reed-like stems, and are useful for covering pillars and bare wall spaces in the warm houses, are seldom out of flower. They grow equally as well in an intermediate temperature as in the warm house, provided abundance of moisture is afforded, chiefly by syringing, during the growing season; the frequent use of the syringe will also keep insect pests, especially thrips and red spider, in check. If the plants have grown too tall or are inclined to be leggy, the top portion of the growths, with aerial roots attached, should be removed. These may be inserted in fibre and Sphagnum-moss close to the rim of a seven-inch pot or pan, in which ample drainage is provided. If placed in a warm and humid atmosphere, where the pots and plants can be sprayed at frequent intervals, the growths should quickly become established. Those Epidendrums which produce side-shoots may be propagated by removing these and treating them as advised for terminal growths.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Peaches and Nectarines.—Where the old fruiting wood was cut out after the crop was gathered in the autumn, there now remains very little to be done in the way of pruning. The trees, however, should be loosened from the walls for the purpose of cleansing and readjustment, and in doing so do not hesitate to cut out superfluous shoots and bare wood which escaped the autumn pruning operations. Gardeners usually tie in far too many shoots on Peach trees and do not allow sufficient space between each shoot for the leaves to function, or for the fruits to develop properly. By far the greater part of the successful training of a Peach tree lies in the system of disbudding carried out on the trees in the early spring; for when carrying out this operation, the grower is planning and anticipating events, rubbing out or retaining certain shoots, having a definite object in view for the future development of the tree. In a fully developed and well furnished tree, a shoot is retained, so near to the base as possible, on each fruit-bearing twig. This shoot is termed "successional" and it is back to this successional shoot that the fruited growth is pruned each autumn, so that there is as little bare wood as is practicable. A certain amount of bare wood is unavoidable in the full development of the tree, but by careful and judicious disbudding and other cultural requirements, the chief of which is abundance of moisture at all seasons of the year, every foot of wall space may be furnished with fruiting wood. Many gardeners tie the loosened branches into small bundles and suspend these at some little distance from the walls, for, they state, it retards the development of the blossom in the spring. What useful purpose this retarding serves I have always been at a loss to appreciate. I would rather get on with the cleansing and tying now, while the weather is open, than put it off until the spring, when the buds are swelling and the weather more severe. What, I believe, is of great importance, is to know "just when" to get on the shelter curtains to protect the blossoms.

Nailing and Tying.—Where the branches and twigs were secured to the walls by shreds and nails, every particle of the old shreds should be removed and burnt; but the nails should remain until the branches are all tied in again. The retention of the nails will save a lot of unnecessary hammering, and those not required can be easily knocked off, the soundest collected and passed through the fire before being used again. Before any tying-in is attempted, the walls should have a thorough cleansing with some reliable spray, such as lime-sulphur (one part in twelve parts of water), or a five per cent. tar distillate put on with some force so that it is driven into every crack and corner to eradicate red spider and other pests. The bundles of branches and twigs may be subjected to a like spraying, or sprayed after they have been secured to the walls. If scale is troublesome try a nicotine spray (one ounce to three gallons of water). The best time, however, to eradicate this pest is towards the end of May and in June, when the tiny scales have left the old shell and are on the move. They simply shrivel up at that time when sprayed with nicotine, and this spray, if applied to the trees in the evening, is not in the least injurious to foliage or fruits. When tying in there should be a space of from four to six inches between the fruiting twigs. The more space the better, as it will facilitate the tying-in of the successional shoots next summer. See that the ties and fastenings do not compress the shoots unduly, or that the branches rub on the sharp edges of nail heads, as both are a fruitful source of gumming later on. It may not be necessary to shorten any shoots on established trees, but it may be necessary in the case of young trees to preserve a correct balance when building up the framework, and in doing so always cut to a triple bud.

Varieties.—Possibly the most popular Peach for out-of-doors is Peregrine, a very free cropper; the colour of the fruit is a brilliant crimson; the flesh is yellowish-white, firm and richly flavoured. Royal George, although a very old variety is still very popular: it succeeds the former in season, and is most reliable. For flavour and reliability the variety Bellegarde would score very high; its season is early to mid-September, and the colour is golden-yellow, almost covered with dark crimson mottling, the flesh pale yellow. Prince of Wales resembles the last-named in colour, but its season is somewhat later; the flavour is excellent, and on the whole it is most reliable.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Primulas.—Primula malacoides and P. kewensis are most serviceable plants for the embellishment of the conservatory and dwelling-house during the dull days of early winter. They require a somewhat dry atmosphere, with plenty of fresh air when the weather is favourable. These Primulas require careful watering at all times, and their roots should be watered only when absolutely necessary, for if overwatered, they damp off. Primula sinensis is now producing its flower spikes. This Primula should be grown in a house having a dry, warm atmosphere and a temperature ranging from 50° to 55°. Liquid cow-manure should prove beneficial in the production of healthy foliage and fine bright flowers.

Begonia Gloire de Sceaux.—This plant delights in plenty of heat while it is making its growth. Plants of this Begonia that have filled their receptacles with roots may require some assistance in the form of liquid manure to maintain active growth, for they are gross feeders. Any check to growth now, caused by starvation, will be very evident when the plants are expected to flower at a later date. Attend to the staking of the plants, and when their flowering stage is reached, maintain a slightly lower temperature with less atmospheric moisture.

The Cold Frames.—Many flowering plants may be grown on in cold frames by covering the lights during sharp frosty weather. Plants which are merely wintered in cold frames are mostly so nearly hardy that it is only during spells of severe weather that the lights need be closed tightly; at all other times admit air night and day, always in proportion to the outside temperature. The chief condition to guard against throughout the winter is dampness, therefore never coddle the plants, but keep them sturdy and healthy by free ventilation. It is also necessary to examine the plants carefully on fine days and remove any dead leaves. Slugs and other vermin, such as mice, often prove troublesome, especially to Carnations, and these should be trapped.

Potting Materials.—The placing of potting materials under cover during the winter and early spring months is an important essential to good cultivation, although this advice is somewhat belated; however, if not already done, it should be attended to without delay.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Peaches.—Houses closed now, or which it is intended to close at the New Year, should now be ready. The roots of the trees should be in a thoroughly moist condition and confined to inside borders. Little or no fire-heat will be necessary during the early stages; it is a good plan to turn on a little heat early in the morning and maintain a gentle circulation throughout the day, regulating the temperature by reducing or increasing ventilation, and shutting off the fire-heat when the house is closed; a temperature of about 45° will be safe throughout the night. Watering should not be neglected, and pure water at a temperature of 80° is best suited for trees at this stage. Houses started at the New Year have something in their favour and will withstand a slightly higher temperature, with air on fine days, but little or no advance on 45° as recommended for earlier trees should be attempted through the night. On very cold nights it is wise to allow the temperature to fall a few degrees lower.

Mid-season and Late Peach-houses.—These should be thrown wide open, fire-heat being out of the question unless there is danger of frost getting into the pipes. As these trees will be retarded until the flower buds are ready to burst, the pruning and cleansing may be held over for bad weather, especially for the latest trees. Any alterations or additions to the borders may be carried out when the weather is mild and favourable to the disturbance of the roots. The best months for planting have gone by, but the introduction of large trees especially may be deferred for a month or more, when the compost, protected from cold, will favour the immediate production of new roots. If the houses are crowded with tender or half-hardy plants, as is often the case, bud-dropping in the spring often results, and proves not infrequently fatal to the production of a crop of fruits. Root-pruning in late houses may still be carried out; this phase of Peach culture seldom receives the attention its importance demands. One often sees trees producing gross wood, and growers endeavouring to check this by cutting away the strong shoots at their base. If it is necessary to check undue luxuriance of growth the roots must have attention, and they may be simply shortened, or the trees lifted, and their roots shortened according to the condition of the trees. When they have occupied the same position for several years without being disturbed, it is necessary to proceed cautiously with repressive measures. It is, however, essential to cut back any strong roots that have gone down into the subsoil, for in no small degree do these promote the soft, unripened growth. It is necessary to keep the roots near the surface so that they can get sun and air, the chief factors in the production of an abundant crop of fruits of good quality.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

The Rock Garden.—Attention should be given to plants on the rock garden each week at this season of the year, the removal of decaying leaves being an important operation as if allowed to remain they soon cause damping and decay of the plants. It is advisable to examine recently planted subjects and make the soil firm about those which have been loosened or partly washed out by heavy rains; if the soil is wet and sticky, place a little dry compost about the plants before firming them.

Herbaceous Borders.—When well managed, herbaceous borders constitute one of the most interesting features of the flower garden. During early winter, these borders do not, in many instances, get the attention they deserve, yet it is at this time that much useful work can be carried out on borders which have not to be re-made. Strong-growing plants, such as Michaelmas Daisies, Heleniums, Helianthus, Phlox, etc., give the best results if they are lifted, divided, and fresh young pieces from the sides of the clumps replanted annually. Dig a liberal supply of well-decayed manure or vegetable matter into the sites they are to occupy before planting, as they are all gross feeders. The dying stems of all herbaceous plants may be cut down to within three or four inches of the ground; in due course, the shortened stems will become loose and can be removed. There is much in favour of leaving the stems full length, especially in cold districts, until the turn of the year, or just before young growth commences. By doing so a considerable amount of protection from frost is afforded, and apart from this, the effect of the various brown-coloured stems is often very pleasing. Yet all gardeners like to see their borders neat and tidy during winter, so well as in the spring and summer. All groups of bulbs should be clearly labelled, so that there will be no chance of damaging the growths before they come through the soil. Bulbs and other plants that have been established for years and which it is not advisable to disturb, should be given a liberal top-dressing of well-decayed manure and old loam. This may be lightly forked in just beneath the surface; it is never wise to dig the soil deeply with a spade around established plants, as this cannot be done without destroying many valuable fibrous roots. Where the construction of new borders is contemplated, or existing ones are to be replanted, no time should be lost in having them deeply trenched and the planting carried out at the earliest possible moment. If such cannot be accomplished by the first week in December, then the planting had better be deferred until the beginning of February. Where collections of Delphiniums, Pyrethrums, Hollyhocks and similar plants are grown, sifted ashes placed around and over the crowns will prevent slugs from eating the tender young crowns and help to protect them during severe weather.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Peas.—If not already sown, no time should be lost in getting the seeds into the ground. Select a round-seeded variety, and sow the seeds in shallow drills in a dry border, preferably facing south. Early Peas do best in a sheltered border in front of a wall. Mice are likely to prove troublesome, and traps should be set for them.

Parsnips.—The decayed foliage and weeds should be cleared from Parsnip beds. Parsnips improve in flavour if left in the ground and lifted when required. Dry Bracken placed over the bed will prevent the ground becoming frozen in frosty weather, and so permit the roots to be lifted when required.

Garden Paths.—If new paths are to be made or old ones renovated, this work may be attended to now. All paths which require levelling should have the surfaces forked over, levelled, and covered with a layer of fresh gravel. In making new paths, make sure that rough stones or brick-bats, clinkers, etc., are placed at the bottom for drainage; while if wide paths are being made, four-inch drain pipes should be placed down the side and catchments placed at intervals to drain off the surface water. If made well in the first place the paths should last for many years, if re-surfaced periodically.

Autumn-sown Onions.—The bed of autumn-sown Onions should be examined and weeded. Spent Mushroom-bed manure, passed through an inch-mesh sieve, may be applied as a light mulching about the plants to afford protection from frost. The ground intended for next year's Onion crop should be trenched now and enriched with plenty of farmyard manure. The surface should be left so rough as possible. After the ground has been trenched, apply a moderate dressing of basic slag.

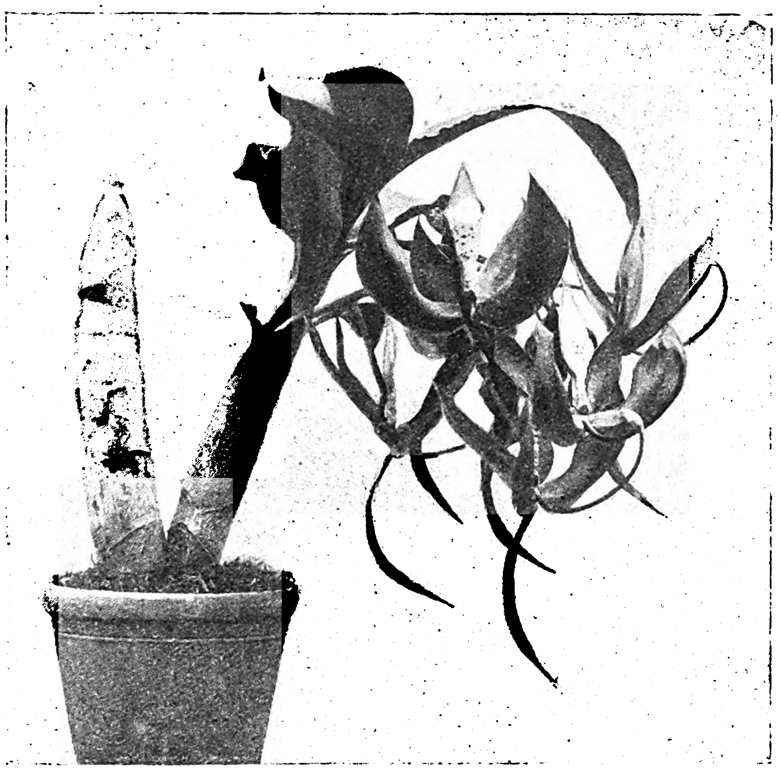

FIG. 203.—CYCNOCHES LODDIGESII.

(see p. 442.)

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Seakale.—Permanent Seakale beds should now be cleared of the old foliage and the crowns covered with Seakale pots, boxes, etc., to exclude light and air, otherwise the growths will not blanch properly. If early forcing is to be done, cover the whole plot to a depth of several feet with leaves or other fermenting material, which will greatly accelerate growth: without this, cutting will not be possible before April.

Forcing Frames.—A quantity of fermenting material should be prepared for these in good time so that it may be turned repeatedly over before use. Where leaves are plentiful they may be used alone, or mixed with rough horse manure, or if leaves cannot be had, manure alone will do, but the heat from the latter is not so lasting as when mixed with leaves. If mixed under cover, watering of the material should be attended to, otherwise burning, as it is termed, may take place.

Morello Cherries.—If the old and superfluous growths were removed from the trees as advised after the crop was gathered, any re-arrangement of the branches necessary should be attended to and the young wood, on which next year's crop principally depends, laid in and secured. Avoid over-crowding the growths, and only in the case of very young trees which have not filled their allotted space, should any cutting back of the new growths take place. Each leading shoot should be fixed securely to the wall close to its apex, or breakage by wind may occur soon after growth commences.

Cordon Trees.—These, both of Apples and Pears, may be attended to at any time now. Remove a few of the longest spurs, and shorten the growths which were cut back when summer pruning. All ties should be carefully tested as they soon rot, and if too tight, they should also be renewed.

Carnations.—Although cuttings of these root successfully at any time of the year, perhaps December is the best time to insert them to secure good plants to flower from next September onwards. Side-shoots about half-way up the flowering stems should be selected, and each removed with a heel; take off the lower leaves and shorten the heel if it is ragged. A box or case placed over the hot-water pipes is ideal for rooting them in, but a fierce heat should be avoided: a temperature of 50° to 55°, with bottom heat slightly higher, is most suitable. Place four or five inches of pure rough sand in the case, and make it very firm, then, with a small, blunt dibber, put the cuttings in only so deeply as to hold them erect: water well with a fine-rosed can, cover the case with glass, and keep it close for a week or so, except for an hour in the morning to dry the glass and freshen the air.

ALPINE GARDEN.

CENTAUREA PULCHERRIMA.

The Centaureas are not among my best garden friends, but I was induced by Mr. Ingwersen to give the subject of this note a trial and have done so with the fullest satisfaction. Partly with the object of checking its reputed ambition to attain a height of nearly three feet, this plant was placed in a hot, dry place, the soil being mostly stones and grit, but of ample depth. With this treatment it succeeded in making a neat tuft of its silvery, deeply-cut leaves, and throughout June and July it blossomed freely. The erect flowering stems hardly reached a foot high, which was just what I wanted on its particular ledge in the rock garden, and their large Sweet Sultan blooms, round as a crown-piece, made a very handsome show in their bright, keen pink against the silvered foliage.

In spite of its woolliness and southern origin, C. pulcherrima has proved winter-hardy here both as regards frost and wet. It promises, indeed, to live up to its designation of being a sound perennial and an ornament of no small value where grey-leaved subjects of gentle colouring are desired. *N. Wales.*

GENTIANA SINO-ORNATA.

May I, as possibly one of the largest growers of this beautiful plant, add a few words to the correspondence that has appeared lately in your columns concerning this species and a fungus which attacks it, in case they may be of use to other cultivators. In this district, in the weald of Sussex, with a lime-free, acid soil, Gentiana sino-ornata is one of the happiest and easiest plants to grow. We have thousands of plants of it, both in the sandy, slightly sticky loam overlying the sandstone of the district, and in the old kitchen garden soil behind my residence.

Like many other Gentians, this plant does not greatly approve of pot cultivation, and is by far happier in the open ground, and here at least does not object to being exposed to sunshine to any great extent, but I must admit that the plants in the kitchen garden which are in part shaded by a hedge running from east to west, are generally slightly better than those which are exposed to all the sun we get. Very noticeable is the objection of this plant to manure in almost any shape or form, especially when growing fully exposed. The foliage looks sickly and yellowish, and the plants of the same age in manured ground, even in ground manured two seasons back, scarcely reach half the size of those in unmanured soil.

Lime is generally, but not always, for some curious and unexplained reason, detrimental to this plant. With us, and in most places known to me, lime spells ruin, but the exception occurs in Major Stern's noted garden, where this plant thrives amazingly in an old chalk pit. I cannot explain this, but suppose there is a perfectly good reason for it, especially as in the garden mentioned many rare Rhododendrons were growing satisfactorily in rather dense shade in leaf-mould very freely intermixed with broken chalk. Possibly the shade was of assistance, too, as I have noticed that Lithospermum prostratum, in nature, to my personal knowledge, is as often as not a limestone plant, but objecting strenuously in most gardens to a limy soil, often succeeds perfectly in limy soil so long as provided with fairly dense shade. All this may raise questions I must leave to wiser heads to answer and return to the subject in hand.

Close by here, in the garden of a friend, and a director of our firm, Gentiana sino-ornata is grown in peaty soil overlying a sticky, grey clay soil which was a few years ago a hopeless swamp. Since trenching operations broke up the hard pan of clay, and part of the clay was intermixed with the peat, this has become an extraordinarily fertile soil for growing many rare plants, and here, too, this Gentian is grown by the thousand in the open ground in long lines, and shows the same abhorrence to any manurial agent. Even places where bonfires have been lit in the past and where probably an excess of potash remains in consequence, are evident to the most inexperienced eye, and the subject of enquiry and comment.

My contention is that the fungus in question does not attack vigorously growing plants, and that I suspect that either lime or manure is present in the soil in question, and that plants grown in full sun feel the effect of these disturbing substances more than those growing in partial shade. Where the position is sufficiently moist, exposure to sun, although making a noticeable difference, cannot be stated to be really detrimental, but partial shade would be a distinct advantage in very dry gardens or in seasons like the past one, when artificial watering became impossible in many districts.

I believe I can truthfully state that our Gentiana sino-ornata did not receive more than two waterings during the two long spells of drought experienced here, and at the time of writing, November 22, I could still pick several thousands of perfect flowers in spite of much bad weather experienced lately, including 12° of frost, and at least one snow shower. Last year, at Christmas time, I was able to fill a large, shallow bowl with perfect blooms, which says much for the vigour and value of this finest of all autumn-flowering Gentians.

In conclusion—a point of great importance, here—we have long discontinued propagating this plant from cuttings of the young shoots in early spring, an easy and ready means of working up a big stock quickly. I find that the resulting plants do not even faintly compare for health and vigour with plants grown from careful spring division, which begin an independent existence with a bundle of the thick, fleshy roots stored with plant food from the previous season. Cuttings have to start without this food reserve and unless grown under absolutely ideal conditions, rarely give a good account of themselves. Indeed, it is preferable to strike cuttings, more or less "Irishman's Cuttings," from the running shoots which carry the flowers, and frequently root on their own account, in late summer, and keep these in pots in a cold frame, well ventilated during the winter. This will result in fleshy-rooted young plants which are capable of growing so well as to almost equal the spring divided plants, and the best advice I can give growers who have had poor success with this plant is to procure strong plants with fleshy roots in March or April and plant these in soil conditions as indicated above, see that the plants do not unduly suffer through lack of moisture, and where moisture is scarce, to provide an approximate equivalent of shade. This, and the absence of lime, should go a long way to prove that the constitution of this fine plant, if rightly handled, is all that could be desired. *W. E. Th. Ingwersen.*

FLOWER GARDEN.

ADLUMIA CIRRHOSA.

Adlumia is a genus of the Order Papaveraceae, which consists of one species only, A. cirrhosa, which used to be called Corydalis fungosa.

This plant, a climbing biennial, is a native of North America. It has slender, twining stems and pale green, tripinnate leaves whose petioles twine and act as tendrils. The small flowers are pale rose-coloured.

Adlumia cirrhosa is half-hardy and an attractive climber for the greenhouse. When grown in the open it is shown to best advantage if it is allowed to climb over a shrub after the manner of Tropaeolum speciosum. In this case the seeds of A. cirrhosa should be sown in a shady spot in the garden during May. Although it is a biennial, when it is in a congenial soil and situation it is as good as a perennial, for it sows itself freely. It does not begin to climb until its second year, and flowers in June.

For greenhouse use, those who are fortunate enough to obtain seeds of Adlumia cirrhosa might try experiments with them in order to induce this plant to flower in gentle heat during the winter or spring. *Victoria Slade.*

ORCHID NOTES AND GLEANINGS.

CYCNOCHES LODDIGESII.

The Cycnoches constitute a very singular genus of deciduous Orchids, whose flowers are of a most peculiar form and character; the male and female flowers are often produced on distinct spikes on the same plant, the former more or less resembling a swan. Certain species are neither showy nor beautiful, yet they are most interesting to many.

Cycnoches Loddigesii, one of the strongest growers and easiest to bloom, is here carrying seven male flowers (Fig. 203) which are four inches across, and have a long and gracefully curved column with sepals and petals of brownish-green, the former with darker spots. The flowers are produced in drooping racemes which appear from near the axils of the leaves at the apical portions of the pseudo-bulbs.

All Cycnoches should be grown suspended at the coolest end of the East Indian house, or the warmest end of the Cattleya house; they have a long period of rest, and during that time—from now onward—will need but little water at the roots to keep the pseudo-bulbs in a moderately plump condition. In spring, so soon as growth commences, the plants should be repotted; turn them out of their receptacles, cut away the majority of the roots—which generally perish during the resting season—leaving just sufficient to help support the plant when repotted. Use two parts of Osmunda fibre and A1. fibre and one part of Sphagnum-moss as a potting compost, mixing the whole well together. Keep the base of the plant level with the rim of the pot, and fill up with compost pressed moderately firm. Water should not be applied for some considerable time after potting; indeed, little is necessary until the new roots have permeated the fresh material, but as growth advances, more should be given, and when the pseudo-bulbs are nearing completion and the plants are in flower, they should not be allowed to become dry.

The foliage of Cycnoches is delicate and very susceptible to thrips and red spiders; to prevent attack by these pests, spray the plants overhead on bright days, and dip them in insecticide once or twice a week.

Cycnoches Loddigesii was introduced into this country in 1530, and I believe has not, until recently, been seen in flower here for many years. The several species of Cycnoches are very tenacious of life, and will live many years under unfavourable conditions. I have exhibited the same plants of Cycnoches chlorochilon for so many as twenty-nine years in London, and although they were not exceptionally vigorous during the later years, they remained perfectly healthy and seldom failed to flower—and this was at Stamford Hill. *F. W. Thurgood, Shepperton.*

INDOOR PLANTS.

ANGELONIA GRANDIFLORA.

Angelonia grandiflora was not introduced into cultivation in Europe until 1897, and so no mention of this charming intermediate-house flowering plant is found in Nicholson's *Dictionary of Gardening*, or in the supplement thereto. Only one species is mentioned in that work—A. salicariaefolia, and the genus is referred to as consisting of "very pretty stove herbaceous perennials."

Bailey, in his *Cyclopedia of Horticulture* describes six species, including the two mentioned above, and states that the genus has in all about two dozen species. Continuing, Bailey writes of A. grandiflora, "It is an excellent plant for winter bloom, particularly the white-flowered variety alba."

I am not personally acquainted with the variety alba, but the type species certainly makes an excellent pot plant, and appears to be of the easiest culture. Seeds sown last spring and later transplanted into "flats" at a distance of two inches apart each way, were stopped once and potted on as required, until they were finally in five- and six-inch pots. A good substantial compost was used on each occasion, and the plants grown on in full sun in an intermediate house temperature. They made sturdy growth, branching freely from the base, and sending up many slender, quadrangular stems which reached a height of eighteen inches or two feet. The entire, slightly-toothed leaves are set closely together along the stems. They are bright green in colour, and somewhat viscid to the touch and are possessed of a peculiar and not displeasing odour. From the axil of each upper leaf appears a solitary flower, poised gracefully at the end of a slender pedicel which does not exceed the leaf. Each flower is about one inch in diameter, irregularly bilabiate, with the lower lip trifid, and the upper, which is smaller, bifid. The four stamens are arranged in pairs.

Violet, perhaps, best describes the colour of the corolla, the throat of which is of a paler hue, with darker markings. A white blotch is present on the lower lip.

The whole inflorescence forms a graceful raceme resembling in general appearance that of Alonsoa. The colour blends charmingly with salmon or with lemon-yellow, and the flowers remain in good condition for a lengthy period. The plant referred to above commenced flowering at the end of September. *T. H. Everett, Pleasantville, New York.*

REINWARDTIA TRIGYNA.

Reinwardtia trigyna is a beautiful winter-flowering plant of the Natural Order Linaceae. It is one of a very small genus comprising three species, all hailing from the mountains of the East Indies, and was introduced in 1799. The specific name trigyna is in reference to the stigmas, which are three in number.

The flowers are a very clear yellow in colour, shading just a little deeper towards the centre where the five obovate petals contract to join in a short tube. They are borne on the current season's growths, either singly or in small clusters. The ovate-oblong leaves are rather a dark green in colour, between two-and-a-half and three inches long. Both the upper and lower surfaces are glabrous.

Cuttings of the strongest and best joints of the old plants should be rooted in spring in a suitable propagating case. They should be grown on in an intermediate temperature until established in six-inch pots. The plants will be much better if encouraged to become bushy by frequent stopping when in the young stage. During autumn, when the growths have been produced, they should receive an abundance of air and sunlight so as to allow them to ripen for flowering during the winter. A temperature of between 55° and 60° should be ample to open the blossoms and prevent damping off.

The most destructive pest of this subject is red spider, and this may be kept in check by adequate syringing during growth, which will also greatly benefit the plants generally. *F. H. Wright, University Botanic Garden, Cambridge.*

PANAX BALFOURII.

In establishments where foliage plants are still grown and cherished, several species of Panax are worthy of consideration.

P. Balfourii is a plant of pleasing habit, its luxuriant foliage draping the rim of the pot and rising to form an irregular pyramid. The orbicular pinnae are deeply serrated, rich green, freely marked with creamy-white, the edges being entirely white; a well-grown plant is a striking ornament for the warm house and valuable for decorative purposes.

With P. aureum, P. fruticosum, and the many forms of the last-named variable plant, P. Balfourii thrives in a mixture of loam and peat, to which may be added a little leaf-soil of good quality, and sand; the plant was introduced a good many years ago from New Caledonia by, I think, M. Micholitz, for Messrs. Sanders.

P. Victoriae is another desirable Panax, often accorded specific rank; it is, possibly, a form of the very variable P. fruticosum. Root-cuttings, sections of the stems, and suckers—occasionally produced by "cut-backs" when placed over or plunged in bottom-heat—provide means of increase; the plants are easily managed and are invaluable where warm-house subjects are staged for effect. *Ralph E. Arnold.*

HARDY FLOWER BORDER.

SISYRINCHIUM STRIATUM.

It may be of interest to supplement the note by *A. D.* on the above plant which appeared on page 303. The accompanying photograph (Fig. 204) was taken by me a few years ago in the nurseries of Messrs. Robert Veitch and Son, Exeter, and it shows a flourishing colony of Sisyrinchium striatum growing in a chipped-stone path, and producing an abundance of flowers. The original plants were growing on the rock-work, but these had all died off after scattering their progeny along the path. The self-selected site evidently suited the plants well, and as this photograph was taken during a prolonged dry spell, the drought-resisting qualities of this species need not be questioned. *H. Greaves, Minehead.*

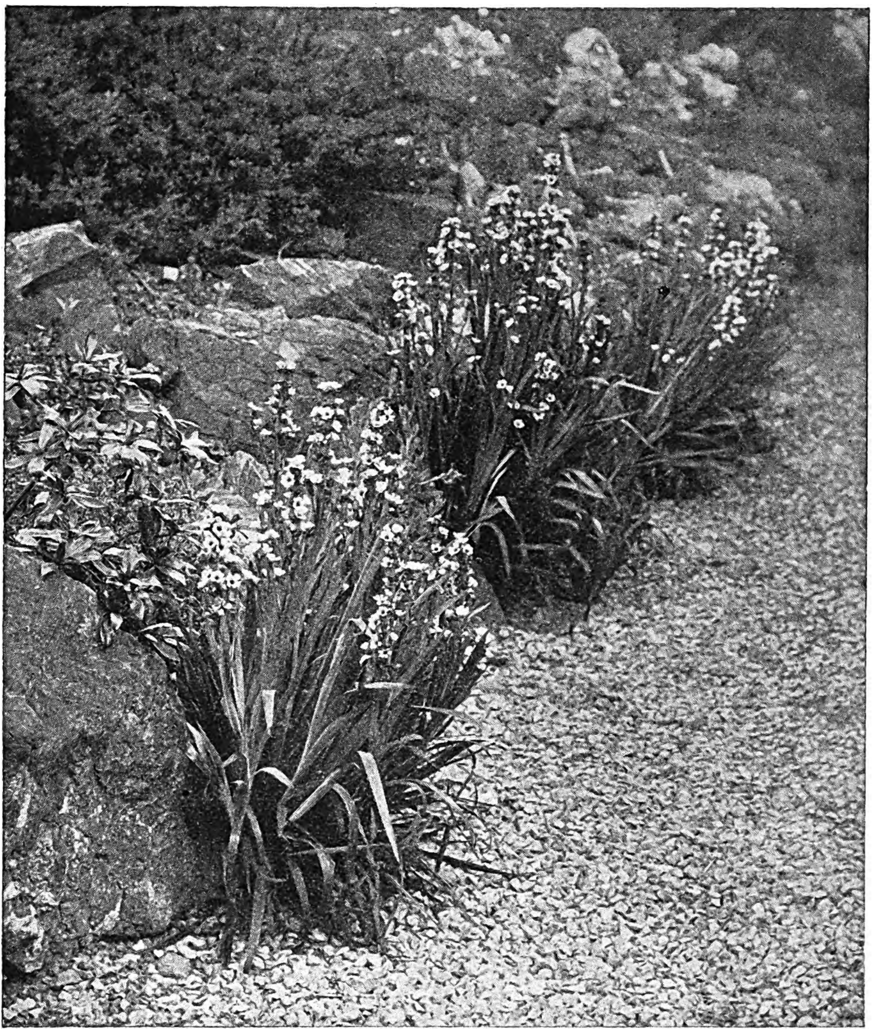

FIG. 204.—SISYRINCHIUM STRIATUM.

LIATRIS.

The genus Liatris is confined to the eastern and southern portions of North America. It comprises some twenty-five species of hardy, herbaceous perennials, as yet practically unimproved by horticulturists, but containing many handsome species well adapted for garden embellishment, and suited for the hardy border, the wild garden, and some species, perhaps, for the large rock garden. It seems probable that the future will bring improved varieties, for already the stately flower spikes are to be found with increasing frequency in the florists' shops of New York and other cities, and they lend themselves to artistic and dignified arrangement. Some of the species are variable in nature and white forms are known as variants from the rose-purple shades which prevail throughout the genus.

Liatris is included in Compositae and all the species are late summer or autumn flowering. They are of erect growth, from a more or less globular tuber, usually simple, but sometimes a little branched. The leaves are alternate or scattered, entire, narrow, and from one- to five-nerved. The flower heads are borne in narrow racemose or spicate, wand-like inflorescences.

The Liatrises are not at all exacting with regard to cultural conditions, thriving in almost any average soil, but responding readily to generous treatment, and only giving of their best when well cared for. They are readily increased by means of division of the roots at the commencement of the growing season, or by seeds sown in the early fall. Plants from spring-sown seeds do not usually bloom the same year. Most species occur naturally on dry, sandy soils, but L. spicata favours moist situations.

Probably the most popular species as a border plant, or for cut flower production, is L. pycnostachya, a native of the prairies from Indiana to Minnesota, Nebraska and the south. The flower spikes attain a height of from four to six feet, and are leafy throughout. The flower heads are about half-an-inch in length and are set densely along the spike for a length of from one foot to two feet; they are of a purple hue.

L. elegans is a showy species well adapted for airy situations; a native of Virginia to

Alabama, Florida and Texas, seldom exceeding a "height of four feet, the four- or five-flowered heads are very numerous, being arranged in a dense spike or raceme, and they are purple in colour.

L. scariosa is a handsome plant about five feet high. The large, twenty-five to forty-flowered heads are arranged much more loosely upon the inflorescence than in the preceding kinds. It enjoys a wide distribution, practically throughout Canada and the United States of America, to the east of the Rocky Mountains, and is quite variable in nature.

Other interesting species are L. squarrosa, L. cylindrica, L. punctata, L. spicata, L. graminifolia, L. acidota, L. gracilis. L. tenuifolia and L. Chapmanni. Lacinaria is a synonym of Liatris. *T. H. Everett, New York.*

TREES AND SHRUBS.

ERICA AUSTRALIS.

ERICA australis has the merit of being both beautiful and interesting. It is beautiful when in flower, and interesting on account of its distribution, form of flowering, and comparative rarity in gardens. These qualities are offset by the fact that the species is not fully hardy in all districts.

This Heath has been described as "ungainly" in habit. Perhaps this is so, when compared with some of the closer-growing species and varieties of Erica; but formality is not always to be preferred in the Heath garden, nor, indeed, in any garden where shrubs are a feature. Although E. australis may be fairly slow-growing, it may ultimately attain a height of at least six feet in certain localities, and if the conditions are suitable it may even exceed this.

Erect, although sometimes contorted in habit, this species appears to ramble on its upward way, rather than to soar up in tier upon tier of growths. Although the young shoots are erect and slightly woolly, these characters do not remain for long. The linear leaves are very dark green (although, of course, lighter in colour on the young growths) and are not above a-quarter-of-an-inch long, sharply pointed, and convex beneath. The arrangement of the flowers forms a conspicuous feature. These are borne from April to June (occasionally so early as March) in clusters of from two to as many as eight, terminating the growths of the previous year. Thus, instead of the type of inflorescence usually associated with the Heaths, the flowers of E. australis hang in clusters from the shoots. Their colour is bright purple, with a strong tendency towards pink. It is a difficult colour to describe, but sunlight causes the pink tinge to be more apparent.

Known as the Spanish Heath, this species also grows in Portugal. It is possible that the natural range is now much more restricted than formerly, but this, so far as the writer is concerned, is merely a suggestion. At all events, the plant succeeds remarkably well in Cornwall and south-west Ireland, and there are certain affinities between the maritime climates of countries on the south-western and western seaboard of Europe.

E. australis has been grown in Britain for over 150 years. It may be grown under quite trying conditions, but is not an object of beauty unless really happy, as the writer saw it not so very long ago in a very sheltered garden some thirty miles from London. A point of interest is that E. australis has been stated to be tolerant of lime, and confirmation of this would be appreciated by those who are fated to grow plants in calcareous soil.

There is a white variety, known as Mr. Robert. This, as might be expected, has leaves of a lighter green than those of the type. It is still rare in gardens and fairly expensive. I believe I am right in stating that the white form was named after the late Mr. Robert Williams, who found the plant in Spain shortly before he was called away in the Great War. If so, this is a memorial as beautiful as it will be permanent in our gardens. *L. B. C.*

MUTISIA DECURRENS.

DURING the past season or two I have been endeavouring, by observing established plants, to discover what aspect this remarkable climbing evergreen shrub likes best. No very definite conclusions have been arrived at, but one thing seems quite obvious, which is that the plant does not enjoy the warmest situation with a maximum of sun. I have an old specimen rambling about some thin-habited shrubs with a south-westerly exposure, but the splendid flowers which are thrust out of the tops of the climber's supports are very apt to droop and sometimes to wither when the August sun is hot and prolonged. But whether this is due to the direct effect of the sun or to a combination of that and a poor, stony, singularly dry root-run, I do not known. However, comparing this plant with some at Bodnant which are on an easterly wall and in cooler and richer loam, I am much inclined to think that M. decurrens, like so many other Chileans, does better with such conditions as the last-mentioned. Mr. F. C. Puddle considers this a thicket climber, and he is doubtless right, but while I do not think the blossoms of the plants in his care are any larger or more numerous than my own, they certainly seem to have a longer season. At any rate, the next plants I secure are going to be tried on a cool side in the sort of place enjoyed by Berberidopsis corallina and Tropaeolum speciosum.

Mr. W. J. Bean, in his admirable description of this remarkable plant (*Trees and Shrubs Hardy in the British Isles*) alludes to a very successfully-grown specimen having had lots of stones placed on the soil about its roots. My veteran—now over fifteen years old—has also a number of stones around it, and I have observed that the suckers by which the plant spreads almost invariably appear from underneath one of these stones. By lifting the latter one may chance to get a nicely-rooted sucker, but it is by no means so easy to induce it to grow when potted-up, although it would doubtless do so in heat. I have kept such rooted off-sets alive for some time, and they have even made considerable growth, but they have a way of collapsing as suddenly as a Clematis will often do. As a matter of fact, much older plants will go off in the same way. One on a wall here expired with tragic abruptness just at flowering time. It was a young and apparently healthy plant, eight feet tall, and in its second flowering season. But I have found one or two other Mutisias quite as troublesome in this respect as M. decurrens. *A. T. J.*

GERMANDER.

THE English name "Germander," applied to various species of Teucrium and more especially to Teucrium Chamaedrys, L., Common or Wall Germander, appears to be derived, through the Low Latin form, *germandra*, from the same root as does "chamaedrys" itself, namely, the Greek *chamai*, on the ground, and *drys*, Oak, the reference being to the little Oak-shaped leaves of this plant, which may be found growing on stony ground, and also on old walls, over the greater part of central and southern Europe and western Asia.

The genus Teucrium, of which the Common Germander is a member, is a rather numerous one, the plants belonging to it varying much in habit. They are, however, well distinguished from other Labiates by the shape of the corolla, which is apparently without an upper lip. This is reduced to two small teeth, one on each side of the lower lip, which has thus five lobes, of which the middle one is large and concave.

The genus is not well represented in Britain. Four species only can be found growing in a wild state, namely, T. Scorodonia, L.; T. Scordium, L.; T. Botrys, L.; and T. Chamaedrys, L., already mentioned. Of these, the first two are certainly native, T. Botrys is doubtfully native, and T. Chamaedrys is almost certainly introduced, but is perfectly naturalised on old walls in a few places.

T. Scorodonia, or Wood Sage, which has rather inconspicuous yellowish-white flowers, is an extremely common plant, too well-known to stand in need of any description. From the point of view of cultivation for decorative purposes, it is quite devoid of interest.

T. Scordium, or Water Germander, is a plant favouring damp, marshy places. It is characterised by its oblong, toothed, sessile or nearly sessile leaves, which, like its weak stems, are more or less covered with soft hairs, and by its pale purplish-red flowers, which are all axillary, and have calyces whose teeth are short and of practically equal length. The plant is by no means attractive in appearance and has a very disagreeable odour. Its distribution in England is interesting and remarkable. It occurs only in a few places. These, such as the Isle of Ely in Cambridgeshire, are mostly situated in the east of England; but the plant has also been found in the extreme west of England, at Braunton Burrows, in north Devon, these two stations having practically the whole width of England between them. Judging from a comparison made between some plants sent me from this latter place, and others collected by myself in the Isle of Ely, there would seem to be some slight differences between the western and eastern forms, the latter being of larger growth and less hairy than the former; although I cannot state whether these differences are in any way constant. The plant, I may add, is fairly generally dispersed over Europe, except in the extreme north, and is also found in Asia.

T. Botrys, or Cut-leaved Germander, also has axillary flowers, but of a more pronounced purplish-red colour. These are arranged in whorls of about six, more or less. It is characterised by the calyx, which is very gibbous and has five practically equal teeth, and by the leaves, which are very much cut up and are rather pretty. Unlike the three other species of Teucrium found in Britain, which are perennials, T. Botrys is an annual. It favours stony and waste places and borders of fields, occurring throughout central and southern Europe. In England, it is to be found only in a few places in the south-east. There is a solitary field near Chipstead, in Surrey, where it grows in abundance, along with another Labiate rather rare in Britain, namely, Ground Pine (Ajuga Chamaepitys, Schreb.)—an interesting association. I believe the field is known to practically every London field-botanist, and is habitually visited when fresh specimens of this rare British plant are required. I have often wondered what would happen if by some unfortunate chance the field was ploughed up or, worse, built upon. It ought, I think, to be acquired by some such body as the National Trust. The danger of losing some of our scarcer species of wild plants is daily becoming greater, and steps ought to be taken to preserve them in their natural habitats. Fortunately, T. Botrys, although certainly a rather pretty plant, is not sufficiently attractive to arouse the desires of those "trippers" who make such devastating and needless raids upon the wild flowers of Britain; and the field I have in mind is, fortunately, somewhat off the beaten track, although Chipstead is now well served by both electric trains and motor-buses from London.

T. Chamaedrys, Wall or Common Germander, bears its abundant, reddish-purple flowers in whorls which form a rather loose, terminal raceme. The calyx is somewhat tubular in shape, and the five calyx teeth are almost equal. The leaves are deeply toothed and wedge-shaped at the base. The rootstock is rather woody. The plant is a very pretty one, suitable for the rock garden or for growing on walls. In Britain it is decidedly rare, being found only in a few places (such as Camber Castle, in Sussex, where I collected some specimens a few years ago), where it has become naturalised on old walls.

It has been stated that Linnaeus gave the name of Teucrium to this genus in honour of Dr. Teucer, a medical botanist. According to another account, he had in mind the plant which Dioscorides stated was first used as a medicine by Teucer, King of Troy, identifying this plant with Teucrium Scorodonia. Whether, assuming that he made it, this identification is correct or not, the fact remains that Wood Sage, in addition to other species of Germander, seems to possess some medicinal virtues. Many species contain bitter principles, and Wood Sage has been claimed as equal to Gentian (the drug is obtained from the rhizomes of Gentiana lutea, L.) as a bitter tonic and appetiser. It was at one time used in Jersey under the name "ambroisie" as a substitute for Hops.

In the past, various species of Teucrium were held in high favour for their medicinal virtues. Culpeper wrote in praise of both Wood Sage and Germander (*i.e.*, T. Chamaedrys), and mentioned numerous ailments which could (were it possible to believe him) be cured by their aid. At one time, Wall Germander was most highly valued as a constituent of the celebrated remedy against gout known as "Portland powder." This consisted of a mixture in equal parts of the leaves and tops of Germander, Birthwort root, Gentian root, Centaury and Ground Pine. The story is that an eighteenth century Duke of Portland received the formula from the son of an Englishman long resident in Switzerland, who had compiled a collection of medical formulae from various sources. Finding the remedy so excellent in its effects, the Duke made the formula public for the benefit of other sufferers, and it was much employed well into the nineteenth century. In addition to taking the drug, a strict dietary regimen had to be observed, which may have had something to do with the efficacy of the cure. In Culpeper's day, Germander does not appear to have been used in treating gout; at any rate, he makes no mention of this "virtue" in his *English Physitian Enlarged.*

Nowadays, as medicinal herbs, all species of Teucrium have fallen from grace, and are no longer used officially. They might repay further investigation from the medical point of view.

For the gardener, who is concerned with the decorative value of plants, the genus Teucrium is not one to be held in very high esteem, although some species are distinctly useful for the rock garden. The leaves of T. Botrys, as already mentioned, are very pretty, but the plant is apt to prove too robust under cultivation. T. Chamaedrys, as indicated above, is a pleasing rock garden plant, and some other perennial species are also useful, including T. montanum, L., which bears an abundance of cream-coloured flowers and grows wild in the mountainous parts of central and southern Europe and Asia Minor, but is absent from Britain. *H. S. Redgrove, B.Sc.*

PLANTS NEW OR NOTEWORTHY.

NYSSA SYLVATICA.

The genus Nyssa is represented by six or seven species of deciduous trees or large shrubs. Four or five are natives of the New World, and two species are found in the east, N. sessiliflora in the Himalayas and Java, and N. sinensis in central China.

Nyssa sylvatica, the Tupelo, or Black Gum Tree of eastern North America, is the only species listed in the catalogues of British nurserymen, and even of this species trees of any size occur but rarely in cultivation in British gardens. Two other species native of eastern North America, N. aquatica and N. Ogeche, have been introduced to cultivation in this country from time to time, but apparently require rather particular climatic and soil conditions for their successful cultivation. In *The Trees of Great Britain and Ireland,* by Elwes and Henry, it is stated there was, in 1906, a tree of N. aquatica growing at Whiteknights Park, near Reading, about thirty-six feet in height. The remaining two species are N. acuminata, growing in the swamps of Georgia, and N. biflora, a small tree found from north Carolina to Louisiana.

Native trees of N. sylvatica in eastern North America occasionally reach a height of one hundred feet with a trunk girth of about fifteen feet. There are three trees growing at Kew about thirty-five feet in height, one of which is illustrated (Fig. 205). The largest tree recorded as growing in the British Isles is at Strathfieldsaye, the dimensions of which were given in *The Gardeners' Chronicle,* 1899, Vol. XXVI, p. 162, as seventy feet high and four feet (not fourteen feet) ten-and-a-half inches in girth.

The great value of Nyssa sylvatica for ornamental and landscape planting lies in the wonderful autumnal colouring of its foliage. One of the trees at Kew is among the first of the trees in early October to develop its brilliant red colouring. There is, however, some diversity of colouring of the foliage on different trees. The leaves of the tree illustrated, for example, remain green until the leaves of the neighbouring brilliantly-coloured tree begin to fall. The predominant colouring of the second tree is rich yellow, tinted with red.

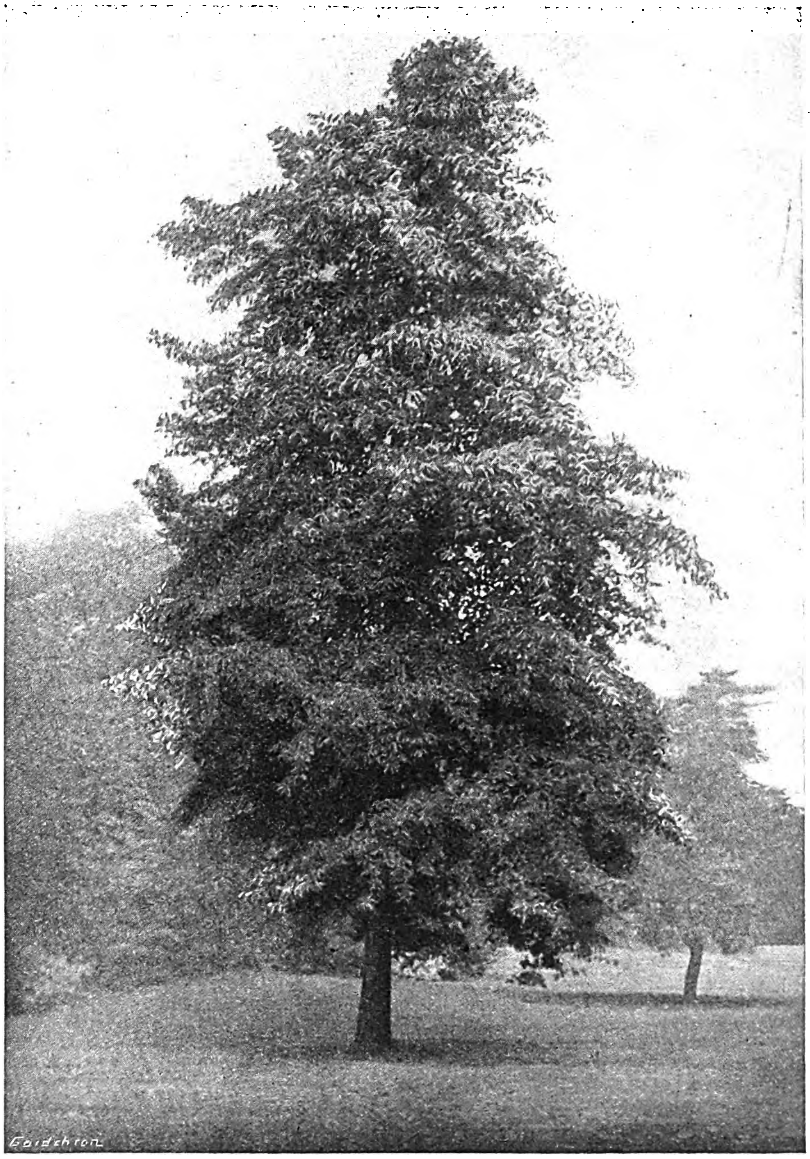

FIG. 205.—NYSSA SYLVATICA.

Small trees of N. sylvatica are listed for sale in several tree and shrub catalogues. Seedlings are obtained fairly readily from imported seeds, but they are by no means easy subjects to manage in the early stages of growth. Small trees in the nursery do not, as a rule, transplant readily, and the safest method would appear to be cultivation in pots and planting, when small, in the permanent positions.

Although considered to be moisture-loving trees, and rather associated in the States with swampy ground, in cultivation the trees thrive under much drier conditions. The tree illustrated is growing in the ordinary dry sandy loam of Kew. *A. Osborn.*

PRIMULA CRISPA.

Farrer, in *The English Rock Garden,* writes of this species: "the commonest garden plant called P. capitata," but no doubt this mistake is due to the fact that P. crispa has always been a scarce plant, and few have seen the two species growing together in gardens. Prof. Wright Smith, in his "Sections of the Genus Primula," places P. crispa in the section Denticulata, although it has a more general resemblance to the P. capitata we all know so well.

P. crispa has now been raised in quantity from seeds collected in Nepal. Flowers have been produced this autumn from seeds sown early in the year. At the Edinburgh Botanic Garden this species was making a nice display in early September, while in the south, plants in cold pits are still busy producing flower stems. It is probable that P. crispa will flower both in spring and autumn, and if so, it is, perhaps the only member of the section Denticulata that does this.

Its chief claim to distinction is that the flowers fill in early at the top and form a fine head of rich, deep purple bells, and one does not find the outer ring and flat head of unopened flowers usually seen in P. capitata. The whole head of flowers faces to one side, as in a garden Pansy, and this characteristic seems to make P. crispa a more effective and showy plant than the better-known P. capitata. The leaves are more like those of our old friend, bright green, serrated, and although there is no meal on them the head of flowers is well powdered with white farina. *T. Hay.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* Publisher; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* Editors. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London: or by telephone to Temple Bar.* 7818.

PROBLEMS OF PLANT LIFE.*

XIV.—Bogs and Bog Plants.

If we take the plant life of the cornfield and pasture land as normal for the herbaceous, and that of our copses and forests as the standard for shrubs and trees, it is clear if plants have the power to adapt themselves to other conditions, that the bog on the one hand, and the desert on the other, may be expected to present to us problems of the greatest interest. Since the term "bog," however, may be used in a variety of ways, and every land has its bog problems, we must limit our observations very largely to the bogs of our own country, and define a bog as a tract of country which is usually under water, largely destitute of useful humus, poorly supplied with the various salts, chemicals and foodstuffs upon which green plants depend, and compelled in consequence to protect its vegetable life on the one hand from a variety of ills and dangers, while on the other it has to adopt special devices to eke out or increase its supplies of plant nutriment. That is, the bog plants may need aid in shielding their organs from excessive moisture, may have to modify their structure, curtail expenditure, and seek other means of obtaining nitrogen and various necessary foods, than those which are in use among plants growing in deep humus and rich soil.

It may be remarked that in the north of England it is customary to call the bog a "moss," and as my personal knowledge of bogs has chiefly been acquired through long study of the "mosses" of Cumberland and the south of Scotland, the fascinating plant life which is found there will be regarded as the type upon which this study is based. Every botanist and student of plant life will remember how he was struck by the comparative paucity of green leaves, the lack of chlorophyl, the modified foliage, the meagre supply of roots, the means of attracting insects, of gathering or throwing off moisture, and a variety of other peculiarities which render bog plants particularly interesting.

Perhaps the point upon which the text books have chiefly insisted has been that which related to the so-called insectivorous plants, and the means they adopt to obtain the supply of nitrogen necessary for their healthy development. So attractive has this subject proved that many eminent naturalists have devoted long years to its study, thus rendering a detailed investigation here unnecessary. We must, however, call attention to a few of the plants. The different species of Sundew or Drosera are probably those which are most widely known. The English name has nothing to do with the sun, the first syllable being a Saxon term denoting endurance. Hence, it may be translated "everdew" on account of the endurance of the dewdrops exuded from the tentacles. These sticky exudations hold fast the insects which alight on the leaves, while they send messages far and wide to say a supply of nitrogen is at hand. With these may be compared the Drosophyllum, or Fly-catcher, found in Portugal and Morocco. Sundews are widely distributed.

Almost equally well known in the north of England, Scotland and elsewhere are the various species of Butterwort (Pinguicula), whose leaves have no tentacles, but a rich supply of glands which serve the same end. The insects which alight are eventually secured by the rolling in of the margins, and the juices utilised as food. In most foreign lands bog plants of many kinds are to be found which in one way or another capture similar prey, and a visit to Kew will well repay the student who would like to study the Pitcher Plants, Venus's Fly-traps, and other allied plants.

By no means rare in many parts of our own country are the curious Bladderworts (Utricularia), so called on account of the curious processes found growing on the aquatic leaves. These bladders capture such tiny creatures as Cyclops, Cypris and Daphnia, known as water-fleas, and Entomostraea, and so long ago as 1875 an article on this subject, by Mrs. Treat, of New Jersey, appeared in these columns as a reprint from the *New York Tribune*. The Bladderworts are widely spread. Kingsley found them long ago in the West Indies, Dr. Gardner in Brazil, while India, Malaya, and other lands have added their quota to our lists.

If we do not possess Side-saddle Plants, Pitcher Plants, and other similar fly-catchers, our bog flora is not without devices of a somewhat similar nature, since the Teazle is able to capture insects in the cup-like bases of the leaves. This modification of leaf-form reminds us of another peculiarity of bog plants, as illustrated by the beautiful Grass of Parnassus. In this case each flower-stalk has a single leaf which acts as a funnel for the collecting of dew or moisture, which it conducts down to the roots. These are few and not wide-spreading, so that the plant, if left without some such encouraging agent, might easily perish from drought. In connection with the Grass of Parnassus, attention should be drawn to the five large scales which alternate with the stamens, and have each some fourteen filaments tipped with a dewdrop. These recall those of the Sundew, and seem to be very attractive to insects, although they are not viscid or injurious.

Another series of plants which have been modified to meet the peculiar needs of the bog are the obscure Charas and Nitellas. In 1774, a botanist named Corti drew attention to a curious phenomenon which he had observed in Chara, which has since been spoken of as gyration, cyclosis or rotation. Under a low power of the microscope an intracellular movement was seen to be going on in the plant, the direction being more or less spiral and limited to individual cells. Balfour remarks that in Chara the axis of the plant is composed of elongated cells placed end to end, surrounded by a number of secondary cells which take a spiral course round the primary cells from left to right. Another peculiarity of this group of plants is that they are encrusted with carbonate of lime which makes them very brittle and causes them to feel harsh, in sharp contrast to the Butterworts and other plants growing near them.

To enable them to throw off excessive moisture the bog plants have evolved a number of different devices in harmony with their individual habits and nature. In some cases the leaves are particularly smooth or unctuous, while in others they are placed at a convenient angle. Sometimes, on the contrary, they are hairy, and this hairiness may be found not on leaves and stems merely, but in the various parts of the blossom. Of special interest are such plants as the Bog Bean and the Bog Pimpernel. These various modifications are eloquent testimony to the fertility of Nature, and show how exquisitely life in its fulness and at its best can meet the demands which are made upon it. They remind us that in quite another direction we may find other tokens of adaptation, as in the resinous glands and waxy secretion of the Sweet Gale, which is often so abundant in boggy places, and the mealiness of the Bird's-eye and Scottish Primroses.

Since we are chiefly concerned with flowering plants, and particularly those which are suitable for a bog garden, we can do no more than mention here the various Rushes, Sedges, Grasses and Mosses which supply the cryptogamist with such unlimited material for study, and the Diatoms, Desmids and Algae which are equally fascinating to the microscopist.

One of the characteristics of typical land plants is the size, colour, texture and stomata richness of the foliage. Looking out upon a garden, meadow or copse, one cannot fail to be impressed with the difference which these present to the eye compared with that of a typical bog. The green of the former gives place to brown and red. Leaves of bog plants are few, small, much segmented, and poorly supplied with stomata. Owing to their environment they function differently, and this different mode of acting shows itself in their structure. If any special work has been done on the stomata of bog plants generally in relation to their life-problems, I have not had the good fortune to meet with it.

Thus far, the treatment of this subject has been entirely of a popular character, with an intentional avoidance of technicalities. Since it might be thought by some, however, that the real problems connected with bogs and bog plants have been avoided, I ought in conclusion to allude to one or two. There is, for example, the question of how plants are to flourish where there is a lack of soil for the roots, an excess of fibrous material such as Sphagnum-moss or peat produces, a deficiency of nitrogenous material of the kind supplied by manures, and the superabundance of acids and toxins. To the foregoing must be added the problems relating to temperature, which, on reflection, will be seen to be serious. Although these problems have been the subject to careful investigation for the past forty years, the researches have been chiefly conducted on foreign soil, and many of the conclusions have only a limited bearing on the questions which perplex the British botanist and gardener. We have learned how to plant bog gardens and obtain satisfactory results, but thus far little has been done in this country to elucidate the subject from the physiological standpoint. Those who may desire some guidance in this direction may be referred to Dr. Yapp's translation of Maximov's work on *The Plant in Relation to Water* (Allen and Unwin, 1929), especially chapter iii and the Bibliography. *Hilderic Friend.*

A WONDERFUL WISTARIA.

Possibly the most wonderful Wistaria in the world is to be found at Ushijima, near the village of Kasukabe, in Japan, an hour's train ride from Tokyo. Tradition states that it was planted over a thousand years ago by the famous priest, Kobo Daishi. Although one cannot place much faith in Japanese traditions, this Wistaria is undoubtedly of very great age. According to the official measurements, the circumference of the much-divided trunk is thirty-two feet and, judging by eye alone, this appears to be approximately correct. The branches are trained over a trellis (Fig. 206) and cover a rectangular piece of ground about four hundred square yards, the longest side being approximately thirty-five yards.

At the time of my visit, the whole of this trellised area was more or less uniformly and closely hung with long racemes of lilac-blue blossom, and formed a truly wonderful sight. Looking upward, one could see nothing but a solid mass of pendant flowers, swaying gently in the summer breeze, the whole being flecked with shadows from the sunlight that filtered through.

The species is Wistaria multijuga, and has exceptionally long racemes. These are stated to be sometimes so much as seven feet in length, but the one I measured was only about four feet. I estimated that the plant carried at least 80,000 sprays of blossom. *Collingwood Ingram, Benenden, Kent.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXVII.—The Plains Again.

It took me a fortnight to prepare my seeds and specimens for the journey to England. The seeds were dispatched by letter post, in thermos flasks and air-tight tins, as quickly as possible. Meanwhile, the weather continued bad, and although we did not have much rain in Sadiya itself, the Mishmi Hills were completely blacked out, and did not appear until after the middle of November; by that time the snow was down to 9,000 feet, and our late camp was, therefore, snowed under.

While marking time in Sadiya we had an afternoon's fishing in the Dibang river, at Deopani Muk (*i.e.*, the point where the Deopani flows into the Dibang), a well-known angler's delight. At the third cast, fishing with a silvered spoon, I hooked a monster, and after one hour and twenty minutes landed a mahseer weighing 50 lbs.—the biggest fish caught in the district for a long time. Beginner's luck!

There were several interesting sub-tropical plants in flower on the plain, including a species of Desmodium, and another Leguminous plant, a climbing Convolvulaceous species, and a handsome violet-flowered herb rather like an Osbeckia. The Desmodium was a small, rounded, compact shrub, about six feet high, growing on the open plain, among tall meadow grasses; it had purple flowers, and leaves coated with long, silky, glistening, silver hairs. Happily there were ripe fruits as well.

On the chapri—islands which are formed in the beds of the big rivers—grew a small underahrub Papilionate, with bright blue flowers. These are rather undersized, and lonely; but if the plant could be persuaded to bear a crop of flowers all together it would make quite a good show. It also bore seeds as well as flowers.

All up the front of the bungalow scrambled a plant with Fern-like foliage and a host of tubular flowers which might have been cut out of dark red plush; these opened in daylight, when the air had warmed up a bit, and closed at night, or when it rained. I never saw the plant growing wild, but was told that it came from the Nowgong district of Assam, some distance down the Brahmaputra valley, where it grew on the edge of the jungle. Some plants had been brought to Sadiya and stuck in the ground, and had flourished. I secured seeds of this pretty cool-house plant.

Finally, there was the Obeckia-like Melastomaceous plant, which grew scattered over the open grassland. The deepest colour forms, with violet petals and bright yellow stamens, were most attractive. The species grows about two feet high—just the single main stem with virgate, axillary pedicels, each ending stiffly in a flower; and the whole thing then withers up in the hot weather, the perennial rootstock sending up a new stem in the following cold weather. This, too, yielded ripe seeds—the seeds are minute and orange-brown in colour, rather like Tobacco seeds in appearance.

We had been in Sadiya less than a week when Buttercup had to leave me to catch his boat in Calcutta; he was wanted at home, and, moreover, there was no doubt that he needed a change of climate. Nevertheless, it was with a heavy heart that I went across the Lohit to see him into his train at Saikhoa Ghat. We had been together through eight trying months, and it would be impossible to do justice to his loyalty, and unselfishness. He was the ideal companion; and only those who have been thrown for any length of time into the society of one man will know what it means when I say that in the whole of that eight months, during which we saw no other white man, we never exchanged an angry word. A week later the party was further decimated (can you decimate a trio ?) by the departure of Luso, who was wanted in Bombay to meet the Roosevelt expedition; I alone now remained of the original Mishmi Hills expedition. Luso, indeed, had been with me just a year, first in the Naga and Abor Hills, then in the Mishmi Hills. In his place I took on a temporary cook-bearer, notorious all over the Sadiya district, known as Suffering John. He had been with every political officer, forest officer and military officer on the frontier for the past fifteen years, because no officer had ever been known to keep him more than three months. He was quite a good cook, and an excellent fellow in camp; but he had one besetting sin—some of us have, sometimes. So soon as he got back to Sadiya from tour, he got drunk; not for the evening, not even for a night, or two, but for a week or a fortnight. And so he wandered from one sahib to another, acting as locum for anybody who was temporarily disabled; he was almost always out of a job, and when he found that I was going to be servantless, he bobbed up from the bazaar one day, before Luso departed, acquainted himself with some of my foibles, and offered his services. So I took him on. Meanwhile, I myself had made no plans; the only certain thing was that until all the recent collection was safely disposed of, I would have to remain in Sadiya. It was my intention, however, to visit Nizamghat and the Abor Hills between the

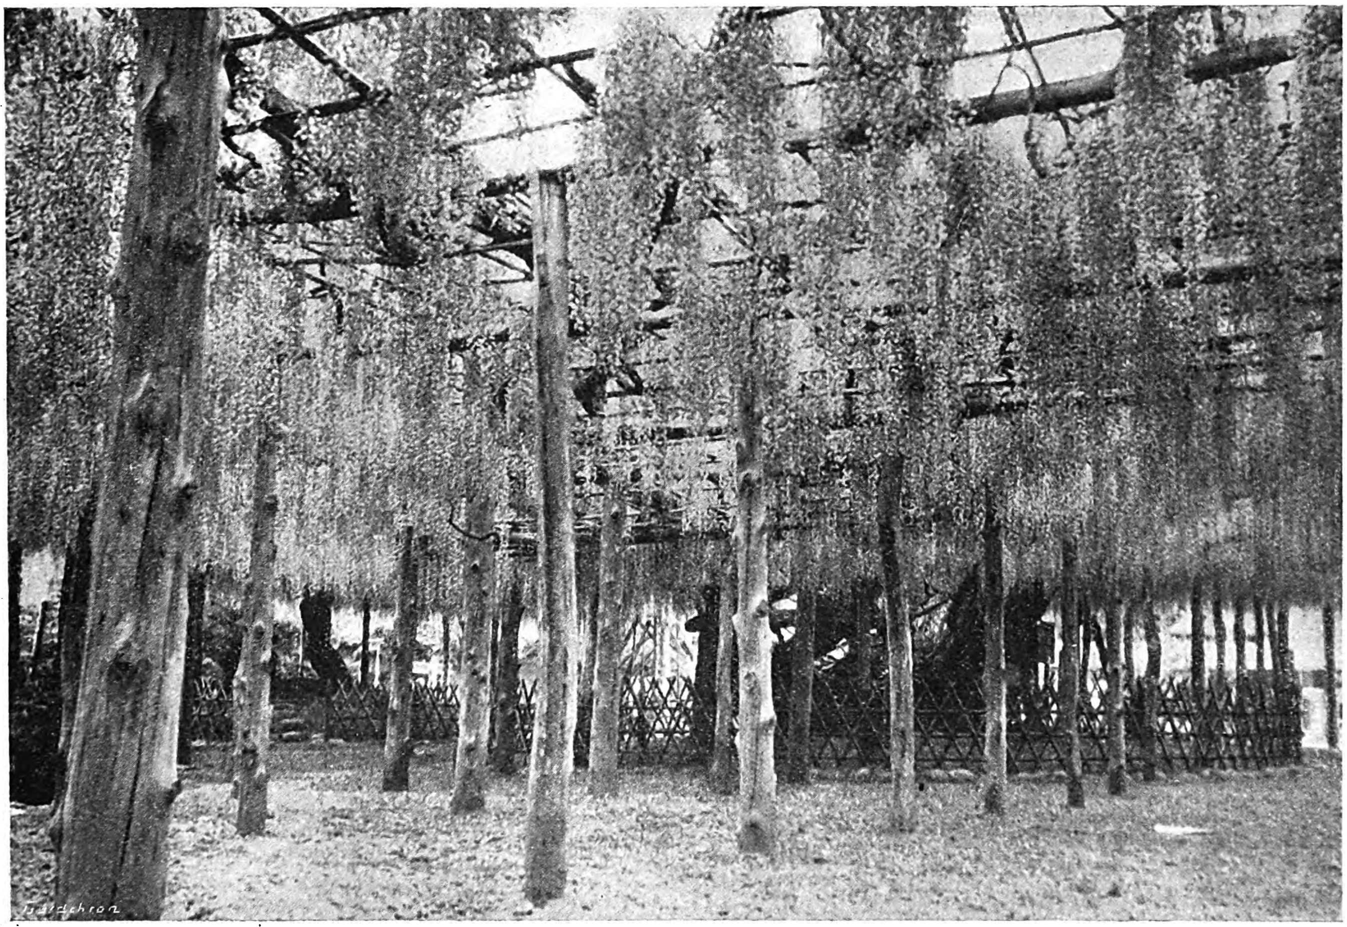

FIG. 206.—AN ELEVEN-HUNDRED-YEARS-OLD WISTARIA, IN JAPAN.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; September 7, 16, 28; October 12. 26; November 9 23 and 30 1929.

Dibang and Dihang rivers, before leaving the district.

One day I went out with the forest officer to see a regeneration area of Holok (Terminalia myriocarpa). This is the most valuable timber tree in the district, and is being extensively planted. It is quite a common tree, but usually grows scattered; occasionally it is almost gregarious. However, it is so much sought after by the saw-mills, that unless steps are taken it will be exterminated in a few years.

The nursery we visited covered about thirty acres, and was being planted up at the rate of five acres a year; but there are much larger nurseries in other parts of the frontier tract. The procedure is as follows. The jungle is felled and burnt in January, the ground cleared and the seeds sown broadcast. The young plants come up thickly, and grow rapidly, the heavy shade choking out all weeds. Weaklings are cut out periodically. Every five years the trees are measured, and the suppressed ones felled. The oldest trees I saw were seven years, and averaged fifty feet high and six inches in diameter at four-and-a-half feet from the ground. Terminalia myriocarpa flowers in October on the Sadiya plain, bearing billows of cream flowers like clouds of Spiraea; it is even more beautiful in November, when the whole tree is loaded with glowing red bunches of winged fruits. Another tree which is being planted, although on a smaller scale, is the Indian Mulberry, Morus laevigata. It has beautiful wood, much used locally for making canoe paddles.

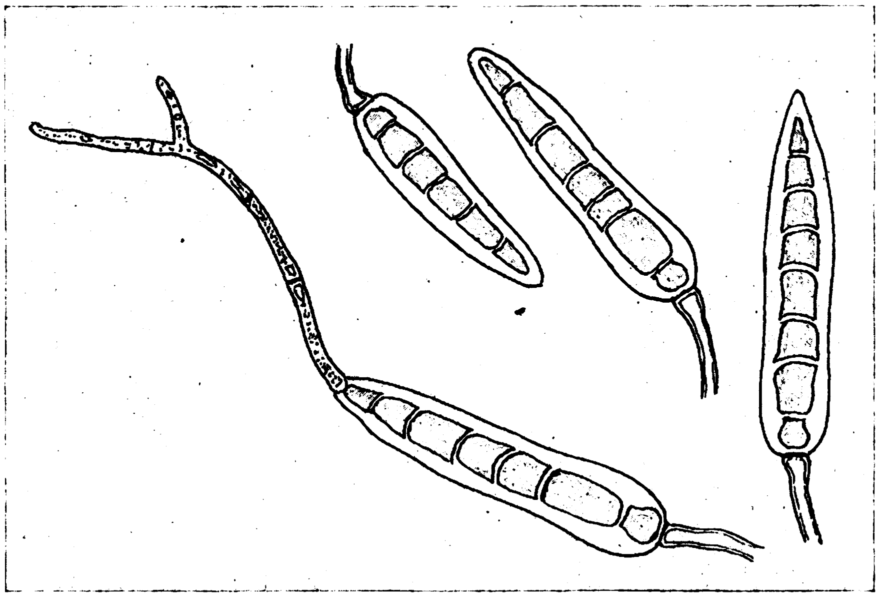

FIG. 207.—SPORES OF CERCOSPORA MELONIS.

(Highly magnified.)

After November 20, the fine weather set in properly; and then, of course, it seemed foolish to leave Assam until the beginning of the hot weather, in March, at any rate. The work which tied me to Sadiya was almost finished, and I began to make plans for a short expedition, lasting, say, two months or so.

We had very heavy mists at night, but usually these were precipitated as dew before morning, and the water dripped like heavy rain from the trees. Dawn, on such mornings, was wonderful. The red sun bulged suddenly up over the hard rim of the plain like a bursting tyre, and bathed the thin mist in a golden wash. The sky changed in a few minutes from pearl-white to pale blue, and the grass glittered with jewels. Then the last shreds of mist were lapped up, the sun gained power, and the growing heat sucked the dew from the trees. A few puffs of cloud came to rest on the blue frontier mountains; and in the brilliant mid-day light, you could count the ranges, which rose one behind the other to the snow-glazed peaks of the Tibetan frontier.

A friend lent me a car while I was in Sadiya, and I drove along the few roads there are. They are only dirt roads, of course, and the car was a marvellous crock—although it went all right when you once started it. That was the difficulty—starting it. You had to hitch up valves with bits of wire, turn the handle, unhitch valves, stamp on everything at once, and turn the handle again, before she would think of going. And the steering wheel! It revolved before your eyes, and if you were not ready for it, landed you in the ditch—for all the roads are raised bunds, with a camber like a railway arch. However, once I got the hang of it I found the car very useful for short botanical journeys into the jungle in the neighbourhood.

After the thrills of botanising in a virgin field, however, there is not much on the Sadiya plain to intrigue the collector. The forest flora of Upper Assam is very much the forest flora of Bengal or of the Duars; and it has been pretty thoroughly explored, from the time of Griffith in the eighteen-thirties to the present day, when forest officers traverse the whole province—or rather, the exploitable part of it. True, the proletariat of plant life—the Mosses, Lichens, Liverworts, Algae and Fungi might yield a harvest of novelties; but botanical collectors always seem to be a little bit shy of these poor relations. In general terms, however, the botanical work to be done in a country like Assam is of a different order—research, observation, and experiment on the known raw material, rather than exploration; work calling for intellectual powers rather than for qualities of endurance.

Still, there is no Flora of Assam yet; and although a retired forest officer had devoted seven years to the preparation of such a work, he has since died, and the whole project has been hung up. From the forest officer's point of view, the materials for a provincial flora probably exist; but from the botanist's point of view, a vast amount of exploration along the frontier ranges needs to be done before such a work could be made anything like complete. At present no more than the plains and the foothills have been touched; and since forest officers are, publicly at least, interested only in "wooden" plants, and the majority of them only in the timber trees among these, much collecting remains to be done among the smaller fry, even on the plains. *F. Kingdon Ward.*

NOTICES OF BOOKS.

Pomologi Beskrivngar över de Viktigaste I sverige odlade Fruktsorterna.

Professor Dahl is well-known as an expert pomologist, and a volume from his hand is, therefore, a welcome event. The present work[*] deals with Apples and Pears, and it is, one presumes, the forerunner of a series dealing with all fruits which can be grown in Sweden.

The reviewer must state at once that he is not able to read Swedish, but, even without this, some facts of interest may be gained from a glance through this well-printed volume and its excellent coloured plates. As to the arrangement, the author follows the course of a full description as established by such great authorities as Mas and Leroy, and references are given to the works of previous authors. A good outline drawing accompanies each description, showing the internal details, core, tube, stem, etc.

The plates follow at the end of the book, and although numbered to twenty-six only, they are each of two pages, and often illustrate four or five varieties, so there are some one-hundred-and-four coloured figures. The colouring and drawing are very good, and in the Apples especially great pains have been taken to render as far as possible the different tones of red and yellow which mean so much to the experienced eye. For instance, Red Astrachan reproduces its natural colour most effectively, and the light bloom is also deftly suggested. The pale creamy-yellow of White Transparent or Lord Grosvenor is skilfully differentiated from the more lemon-yellow of Lord Suffield.

Perhaps the part of greatest interest for the non-Swedish reader is the origin of the various fruits described, and here I am confirmed in my view that the best all-round fruits have also the widest range of climatic endurance. Of our British varieties which are at home in the Swedish climate is found the irrepressible Bramley's Seedling and its opposite dessert number, the Worcester Pearmain. Lords Suffield and Grosvenor, although of British origin, are of Russian blood; and I am not therefore surprised to find them also figuring well. The American Wealthy, well-known to be very hardy, is in the collection, as are Melon Apple and Rhode Island Greening. The last-named seldom reaches perfection in my experience in this country, and it would seem that more sun can be relied upon in Sweden than the usual British allowance.

As would be expected, many German Apples figure in the collection, and among the native Swedish varieties Gravenstein and Akero are well-known to us in England.

Turning to the Pears, we find the French and Flemish varieties which have for a hundred years been the standard varieties of western Europe predominating. Williams's Bon Chretien and Conference from this country apparently thrive, as do some of the American varieties, such as Clapp's Favourite, Hodge and Seckle.

It is interesting to see a good figure, the first, I believe, of the Pear named Moltke, which was shown at the recent R.H.S. Fruit Show, and to learn that its name commemorates a Danish Minister of State, and not the better-known German strategist. This Pear has many garden merits, good habit, free crop, and the flavour is also good, so that it may ere long be added to our list of October Pears.

Up to the present, the only Swedish work which was available was the *Svensk Pomona*, of Eneroth, published in 1864-66. The plates of this work are very poor and badly drawn. Professor Dahl's work thus comes as a valuable addition to our reference works, and will be welcomed by students of systematic pomology. *E. A. B.*

A German Cyclopedia of Hardy Plants.*

The first two volumes of a new cyclopedia of hardy plants, by the well-known German horticultural writer, H. R. Wehrhahn, have just been published by the Berlin firm of Paul Parey. The book is stated by the publishers to be intended for gardeners, trade growers, garden lovers, students and designers; and, indeed, its scope is wide enough to embrace all these classes of people, to whom, doubtless, a complete list of the hardy plants now known and cultivated in the northern hemisphere is bound to be of service. In view of the enormous developments which have taken place in this realm of gardening in the last quarter-of-a-century, and especially since the war, to undertake so formidable a task required considerable courage, to say nothing of a large and varied experience, coupled with accurate and extensive botanical knowledge. If, in such a work, absolute accuracy is not to be found, this is but to admit that author and printers are human; and there is much which can be sincerely written in praise of the work so far as it has gone. Efforts have been made, attended by a considerable measure of success, to bring the information right up to date, and to include as many as possible of the most recent specific and varietal introductions; the matter is written succintly, and the photographs excellently taken and reproduced in first-class style. To the busy reader, however, the book has one fatal defect: that the species and varieties are not given in alphabetical order. Doubtless, when the book is completed, there will be alphabetical indices, but we greatly prefer the system adopted by L. H. Bailey, in his *Standard Cyclopedia of Horticulture*, of giving for reference, at the top of every generic section, a complete alphabetical list of all species and varieties in the genus. Purely descriptive matter is, perhaps, best grouped otherwise, untrammeled by a rigid system of initial letters; but for rapid reference, nothing equals alphabetical arrangement. Furthermore, the method adopted, by enabling the reader easily to "run down" a plant of which he is desirous of ascertaining the name, although ingenious, would not, we think, appeal to everyone as being particularly simple; and as the purely botanical descriptions must necessarily be supplemented by fuller information, the botanical notes, being separately grouped, tend rather to take extra space than to save it. We venture to think that for purposes of rapid and accurate identification, a small, but clear, drawing of each important species is the best method, especially in a work avowedly intended to be useful to readers who have not the advantage of very advanced botanical knowledge.

The illustrations, although excellent in themselves, are somewhat partial, and in some cases inexplicably large, occupying considerably more space than the importance of their subjects would appear to justify. For instance, Muscari Aucheri var. praecox occupies a whole page, and M. botryoides nearly half; Galanthus has three illustrations devoted to it, even Galtonia has one, but there is none of the large Asparagus genus, and none of Calochortus.

The book is arranged by families, beginning with Typhaceae. On page 30, the Liliaceous family begins, and occupies nearly 160 pages, so it will be seen that adequate space is devoted to each section. The work is to be completed in about ten parts, which, if all about the same size as the first two, will comprise together something like a thousand pages. When the index makes its appearance, and the separate parts can be bound in a convenient form (as they are now, wrapped in paper, they drop to pieces by the sheer weight of the art paper they are printed on) the work will take its rightful place on the horticultural bookshelf as a painstaking, serviceable volume, which will probably rank for many years to come as the best reference book on the subject of hardy plants. Few authors expect, fewer still attain to, a higher ambition than this.

---

* *Die Gartenstanden*, by Von. H. R. Wehrhahn. Vols. 1 and 2 (to be completed in about 10 volumes). Berlin: Paul Parey. Price per vol., R.M., 5·20.

CERCOSPORA LEAF SPOT ON CUCUMBERS.

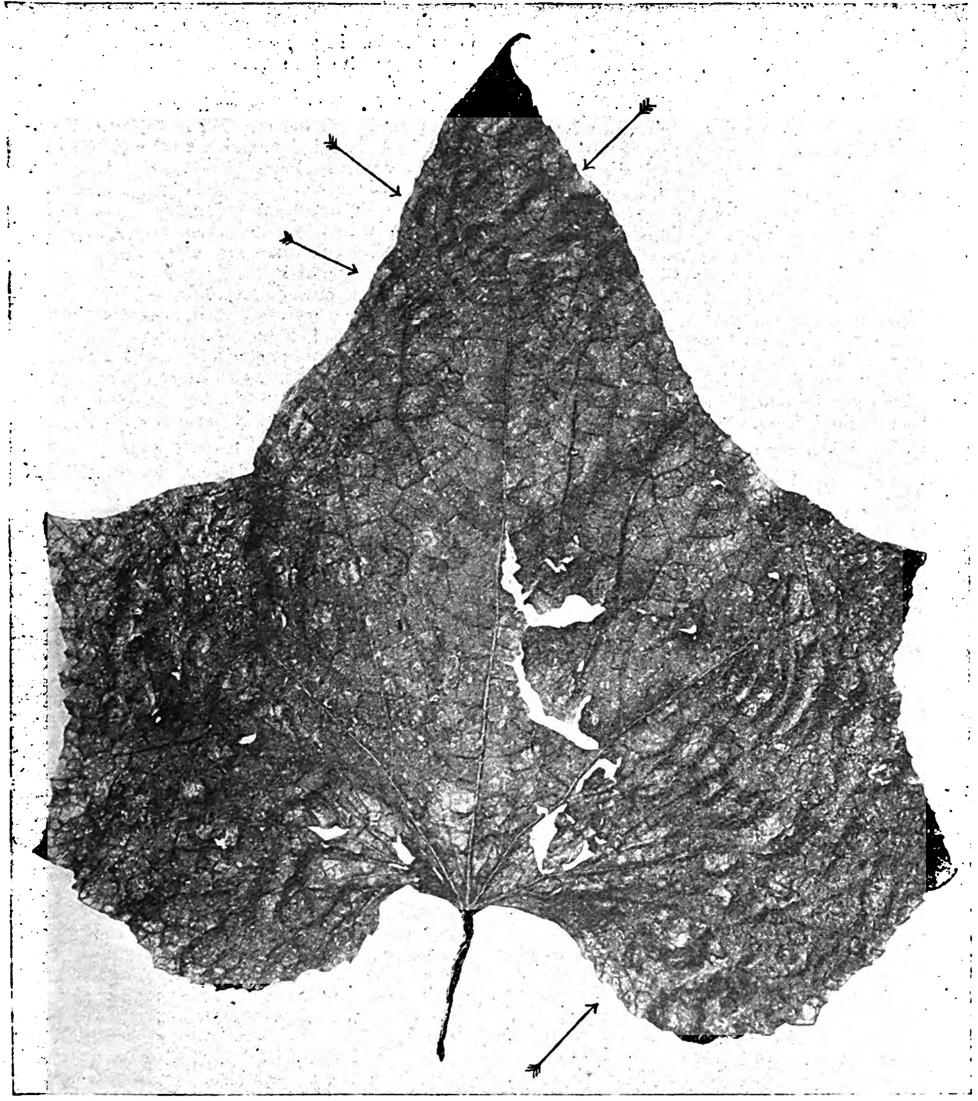

FIG. 208.—CERCOSPORA LEAF SPOT OF CUCUMBERS.

Diseased leaf showing water-soaked and brown spots.

THE disease attacking Cucumber and Melon plants caused by Cercospora melonis is, fortunately, rare in this country at the present time. From 1896 up to about 1907 it caused considerable destruction in certain districts, but the introduction of the variety Butcher's Disease Resister, which is immune to this disease, together with certain precautions in culture, succeeded in checking the spread of the disease. Since that time very few observations of the disease have been recorded, and it was considered to have almost entirely disappeared. During this year, however, there have been several records of the trouble, and it is important that anyone growing Cucumbers or Melons should constantly watch for symptoms of this malady so as to avoid further epidemic outbreaks.

Once infection has occurred in a house the affected plants go off with great rapidity, and it is but a matter of days before the entire crop may be destroyed. The first symptom of disease is the appearance of small, pale, water-soaked spots on the upper surface of the leaves, which increase in size and number, often coalescing, turning grey, and finally brown in colour. The shape is irregular, but the outline quite definite (Fig. 208). Leaves so affected rapidly wither. Microscopic examination of the spots shows the upper surface to be covered with the filaments and spores of the fungus. The latter are comparatively large, cylindrical bodies, narrowed at one end, usually having seven transverse walls, but occasionally so many as eleven of the latter have been observed. By means of these spores infection spreads rapidly—they are blown about and their dissemination is hastened by insects and also by necessary handling of the plants during cultural operations. Healthy leaves are infected by means of the germ-tube produced from the narrow end as shown in Fig. 207.

Rapidly-growing plants are, of course, extremely susceptible, and conditions of high temperature and humidity aggravate the trouble. Control, therefore, depends mainly upon judicious ventilation to regulate the humidity of the atmosphere, and on the most careful use of nitrogenous manures. Diseased leaves remain potential sources of infection, and should be carefully removed and burnt. Prompt spraying of slightly diseased plants with liver of sulphur is recommended as a means of control. When the crop is severely affected and it is decided to burn all the plants, thorough precautions should be taken to ensure that the disease shall not appear again. Every part of the house should be sprayed with some solution capable of destroying the fungus spores. In addition, the soil should be sterilised by some method or other; if the quantity to be treated is not too large the formalin method is probably the most effective. Descriptions of washes to be used and methods of application can be best obtained by consulting Dr. Bewley's book on *Diseases of Glasshouse Plants*. *D. E. Green, M. Sc., Wisley.*

THE GENUS PRIMULA.

(*Continued from p.* 429.)

SUFFRUTESCENS (A. Gray). Shrubby P.
(Cuneifolia).

A BEAUTIFUL, evergreen, sub-shrubby perennial sub-species of P. cuneifolia (Ledeb.), with woody, branching stems which creep on the surface of the soil. The leathery leaves are produced in dense tufts or rosettes at the ends of the branches, and have wedge-shaped blades, blunt at the tip, tapering at the base into winged stalks, in all one inch to three inches long; margins towards the upper half of the leaf furnished with four to seven sharp teeth; both surfaces more or less smooth and non-mealy. Flower stems two to five inches tall, bearing an umbel of two to six erect, pink or reddish-purple blossoms with a yellow eye, on stalks about half-an-inch long. Corolla about one inch to one-and-a-quarter inch across, divided into five egg-shaped, deeply cleft, shallowly-bifid lobes; tube cylindrical below, dilated upwards, longer than the calyx. Flowers in June and July. Introduced in 1884. *Gard. Chron.*, 1912, Vol. LII, p. 226, Fig. 99.

Grows in exposed situations on rocky slopes in the Sierra Nevada of California at 9,000 to 10,500 feet above sea-level.

Culture: Grow it in good friable loam and peat in a well-drained, half-shady spot, with underground moisture and protection from wet in winter by a pane of glass overhead.

SULPHUREA (Craib). Sulphur P.
(Petiolaris-Sonchifolia).

A dwarf, tufted, perennial species with broadly oval or egg-shaped, almost stalkless leaves from one inch to two inches long; margins furnished with fine teeth; upper surface more or less smooth, underside densely coated with sulphur-coloured meal. Flower stem very short or quite wanting. Flowers fairly numerous, borne on stalks half- to three-quarters-of-an-inch long, springing from the short flower stem or crown of the plant. Corolla about half-an-inch across, probably pale purple, with broadly heart-shaped, entire or lacerated lobes. Flowers in February. Not in cultivation.

Grows in damp, rocky soil on the Kumaon Himalayas, at Suring, at about 4,500 feet above sea-level.

Culture: As for P. petiolaris.

SYLVICOLA (Hutch.). Sylvan P.
(Cortusoides).

This beautiful sub-species of P. cinerascens (Fr.) which is best treated as a biennial in cultivation, is very closely related to P. sinomollis (Balf. f.). It has a somewhat fleshy rootstock which produces sparse tufts of thin, spreading and drooping leaves, with oblong-elliptic blades six to eight inches long, rounded at the tip, heart-shaped at the base, borne on hairy stalks from four to six inches long; margins cut into small lobes which are minutely toothed; both surfaces finely downy, nerves hairy on the underside. Flower stems numerous, fifteen to twenty-four inches tall, downy, bearing six to seventeen superposed umbels of six to nine, rose-purple, fragrant blossoms with a yellow eye, on downy stalks about one-and-a-quarter inch long. Corolla about three-quarters-of-an-inch across, divided into five spreading or slightly recurved, broadly egg-shaped-oval, widely-notched lobes; tube cylindrical. Flowers from April to June. Introduced in 1913. *Gard. Chron.*, 1916, Vol. LIX, p. 318, Fig. 139.

Grows in sheltered, shady places on the margins of thickets, etc., in Yunnan, at 6,000 to 8,000 feet above sea-level.

Culture: Good, rich, somewhat heavy loam and leaf-soil in a cool, shady spot, with protection from damp and severe frost in winter, should suit it.

SZECHUANICA (Pax). Szechuan P.
(Nivales).

A smooth, deciduous, non-mealy perennial species with a tuft or rosette of thin, membranous leaves two to three inches long and three-quarters-of-an-inch to one inch wide, with oval or oblong-oval, pointed blades gradually narrowed into a winged stalk as long, or shorter than, the blade. Flower stem stout, six to ten inches tall, bearing an umbel of six to ten violet or yellow blossoms. Corolla about three-quarters-of-an-inch across, with oval, reflexed, entire lobes; tube about three-eighths-of-an-inch long, dilated at the throat, about as long as the calyx. Flowers in June and July.

Grows in damp alpine pastures and on the margins of thickets, near Tatsienlu, in western Szechuan, western China, at 9,000 to 13,000 feet above sea-level.

There is a robust, unnamed form, from south-eastern Tibet, with flower stems up to three feet tall, bearing one to three superposed umbels of pale yellow, fragrant flowers.

Culture: As for P. Maximowiczii.

TALIENSIS (Forrest). Tali P.
(Petiolaris-Sonchifolia).

A beautiful dwarf species with the whole of its foliage, stems and calyces covered with short, stiff hairs. The egg-shaped-spathulate leaves, produced in tufts, are from one to one-and-a-half inch long, and taper at the base into a broadly winged stalk; margins furnished with deeply-cut, irregular, saw-like teeth. Flower stem stout, one inch to three inches tall, bearing an umbel of two to six white or pale blue, yellow-throated blossoms, on stalks half- to three-quarters-of-an-inch long. Corolla slightly concave, about three-quarters-of-an-inch across, with broadly egg-shaped lobes, trilobed at the tip; tube cylindrical below, dilated upwards, about half-an-inch long. Flowers in September.

Grows in moist, open, stony pastures on the eastern flanks of the Tali range, and in similar situations on the mountains of the Shiveli-Salween divide, in Yunnan, western China, at 10,000 to 11,000 feet above sea-level.

Culture: Good, friable, gritty loam, in a moist, open spot, with protection from damp in winter, should prove suitable. *A. W. Darnell.*

(*To be continued*).

HOME CORRESPONDENCE.

Basket Begonias.—Wire baskets filled with suitable plants are often used and valued when suspended for adorning glass structures. Among many subjects suitable for this purpose, trailing Begonias are worthy of special note. The following varieties did well with me during the past summer: Fleur de Chrysanthemum, Lena, Gladys and Mrs. Bilkeny. The first-named is very free-flowering, with pale pink blooms and, perhaps, a better bushy habit than the other varieties mentioned. Lena and Gladys carry blooms of a crimson shade, the former slightly darker than the latter. The flowers of Mrs. Bilkeny may be described as of an apricot shade—they never fail to call forth comments of praise. The growth of this variety is stronger than that of any of the other sorts, with correspondingly slightly larger foliage. Young plants give the best results, although occasionally old roots persist awhile and give excellent displays. Propagation of new stock is by cuttings and is not difficult. *C. Turner.*

The Need of Education for Gardeners.—I am sure our Managing Editor will allow me to recall that in the dear old *Gardeners' Magazine* of nearly forty years ago, when he was an aspiring young sub-editor and I was an aspiring young writer, I brought this matter up time and again, urging, among other things, examinations which tested practical as well as theoretical knowledge. I did not, and do not now, dispute that there are many cases of under-payment; but I maintained that the young gardener who made a point of mastering his craft, and at the same time keeping abreast of scientific progress, would in most cases get a satisfactory reward. It is "forty years on" and what do I see? A hundred good posts where in the old days there was scarcely one; public authorities vying with each other to make beautiful parks and gardens, with—*ipso facto*—posts for intelligent and well-informed gardeners; school gardens and demonstration allotments in every county, with openings for instructors; research stations steadily multiplying. And remember, this is not finality. It is, indeed, little more than a beginning. Mr. Good's letter, on page 411, is admirable, but where he states "very necessary" in connection with the study of botany, etc., I would use "very desirable," because I think that many young fellows are apt to think they can do nothing worth doing without outside help. They are wrong; they can do a great deal. At the least, by reading they can put themselves in the way of being able to take swift advantage of tuition when the chance of getting it comes. Kerner and Oliver's *Natural History of Plants* remains a gold mine still unexhausted. De Vries's *Species and Varieties* is as fascinating as ever. Two invaluable small books are the late W. Bateson's *Methods and Scope of Genetics*, and Sir Frederick Keeble's *Plant Life*. The latter has given me many hours of delightful reading and re-reading. It is packed with information and written in that suggestive, imaginative and stimulating style of which Sir Frederick is the envied master. And I positively must mention Mason and Dow's *Rural Science* because of its value in pointing out simple experiments. These books are but a few of many which open up avenues of pleasant and fruitful study. And may one who has reached the veteran stage, and perforce gone into retirement, add that good as the old times were, the present are still better? Never was life so full of zest, so rich in opportunity, as now. Never was gardening in particular so fertile in promise as it is to-day. *W. P. Wright.*

—— I note, in your issue for October 26 and November 9, respectively, articles on "The Need of Education for Gardeners." In thirty years' experience, I have met gardeners of various ages and experience who had not gained one degree of knowledge from study, but who were, and are, some of the best workers and gardeners in the country. The best education any young man can obtain to fit him for a good post is to fill a situation under a good all-round gardener in a good establishment, as an apprentice, improver, journeyman and foreman, say, three years in each capacity in various establishments. He will then, without a doubt, be qualified to fill a head situation. In many gardens digging, brick-carting, wood chopping, etc., are included in the gardener's work, and such establishments have been the means of discouraging many a young man who has been unfortunate in falling into the trap of misrepresentation. For myself, I was fortunate in getting a fairly good education. I served my terms in gardening as mentioned. I kept a diary of work done for three years; this improved my handwriting, and I also made a point of study at various times. But I discovered too much learning would have made me mad, and all work and no play made me a dull boy. I bought *The Gardeners' Chronicle* for 3d., and *The Garden* for 2d. before 1914, so I fail to understand how they cost Mr. Cuthbertson's friend 1s. per week, if his friend bought them before 1914. I quite agree with Mr. Cuthbertson that the old order of things has changed, but not to improve the gardener's lot. No gardener, through study or education alone, will ever fathom the practical side of horticulture. *Thomas William Mead, Hylands Park Gardens, nr. Chelmsford, Essex.*

Spanish Gardens.—In your appreciative review of *Spanish Gardens*, in your issue of November 16, I notice your critic doubts "if the beautifying of the earth with trees and flowers makes any appeal to the Spaniard, or even to the authoress of this book." As the requirements of the irrigated garden are so foreign to garden-lovers accustomed to our rainy climate, may I quote a passage from my book in answer to your critic's question.—"It has been said that Spanish gardens are curiously lacking in the colour of flowers; that green is their predominating note. Green is certainly a favourite Spanish colour, and this is not to be wondered at in the brown arid country of the central plateau, where the parterres of Aranjuez and the Escorial are filled with endless geometric complications of clipped Box. But the Moors of Andalucia, much as they valued green for their turbans, had other ideas for their gardens. The deep purple blue of the Iris, *azul*, was the colour of Moslem Spain. Azure and sage-green, turquoise and white, their cool, delicious colour scheme, can still be seen each April in the Secano (of the Alhambra) when the Irises are in bloom." *Constance M. Villiers-Stuart, Beachamwell Hall, Swaffham, Norfolk.*

Odontospermum maritimum.—This old plant, which has been in cultivation for three hundred years, has received a good deal of notice lately in *The Gardeners' Chronicle*, and if it does not deserve to be classed among the elect, it has some valuable attributes. I used to grow it years ago as Asteriscus maritimus, and have always found it one of the best of drought-resisters, and a most persistent flowering subject from spring to late autumn. A week or so ago, a clump was still ablaze with its golden Daisy flowers, even although we had had sufficient frost to put all its late-flowering companions out of bloom. That plant had never been a day without a mass of blossom since May, and that during one of the most trying summer on record. O. maritimum varies a good deal in stature, six inches being, perhaps, the average height attained by the upright flower stalks. The latter, like the close tuft of woolly, grey leaves, rise from a woody base which seems to be able to withstand severe frost provided the root-hold is dry and stony. The plant sometimes called O. m. var. littoralis, which one may come across on the limestone in parts of southern France, does not appear to differ in any important particulars from the form commonly grown and which is a native of more easterly regions of the Mediterranean. *North Wales.*

Lonicera nitida.—Inasmuch as nurserymen have in many cases raised large stocks of this shrub in anticipation of a considerable demand for it as a hedge plant, the letters of Mr. Fred J. Chittenden (p. 391), and Sir Frederick Keeble (p. 411) are of considerable importance. Perhaps I may describe its behaviour in East Kent. It was badly cut by the severe frosts of last winter in several places on the Thanet Beds. It also suffered on the Leas at Folkestone, with a south aspect and chalk subsoil. But on, perhaps, the coldest (certainly the most exposed) site of all, a high terrace on the chalk at Dover, it passed through the winter unscathed. In this case the soil was well manured, and so far, supports Sir Frederick's recommendation to try manuring. But in naturally fertile soils I can imagine this being easily carried too far, with the result that very succulent shoots, particularly liable to injury from frost, are produced. This would be the more likely to happen in districts of heavy rainfall. It is a case for judgment. Each planter will be swayed by local conditions. I may add that I have seen very few cases of the shrub being killed outright. Where there has been injury the plants have been cut back more or less severely, and afterwards have broken out again and made two to three feet of new growth during the ensuing summer. *W. P. W., Whitstable.*

Grey Squirrels.—The ubiquitous grey American squirrels are rapidly increasing, and have settled firmly in the counties adjacent to London. It would appear that it was from Regent's Park that these creatures originally spread; and to-day they are a source of grave concern to very many gardeners, amateur and professional. Here, on the Hertfordshire and Buckinghamshire borders, they are very numerous. The saddest part of their invasion is the extinction of the pretty brown English squirrel. Compared with our little native friends, the grey ones are more pugnacious, and being much larger require more food, and they get it. Unlike the brown squirrel, they do not hibernate in winter, although very severe weather may cause a few to lie up for a week or so. They breed rapidly, which only adds to the gardener's difficulties. Quite recently I tried to prevent a large squirrel from reaching a wood, curious to know what the "ball" was it had in its mouth. Being hard pressed, it dropped the ball, and I saw it was a young squirrel, which rapidly made off at right angles, and both got away. The mother was leaping yards at a time, and carrying her young like a cat. Their menu is extensive, and will include Pears and all wall fruits, Nuts of every kind, seeds of Hornbeam and Sycamore, Acorns, Fir cones, and pickings from house refuse. Systematic methods of keeping their numbers down have had to be adopted in many places. The Watford Borough Council's park authorities, in answer to complaints from gardeners adjacent to Cassiobury Park, had to destroy a large number, and at Latimer over one hundred were shot last spring. Grey squirrels are very wary of traps, but I have caught them in the ordinary square wire rat trap placed near a refuse bin. When cornered like this they are exceedingly savage, and care is needed in picking up the trap. There should be a certain value in a good skin, and the knowledge that a great many grey squirrels are now being destroyed annually should bring a demand. *G. W. Stacey, Chorley Wood Cedars, Hertfordshire.*

Calanthes with Flowers and Foliage.—I was much interested in the remarks of *J. C.*, relating to Calanthes retaining their foliage while in flower (p. 411). I can assure him that this indicates generous cultivation—which is quite essential if one desires to produce flower spikes five and six feet long. It is plain proof that when the plants retain their foliage all has been well during the growing season, such as freedom from insect attacks, due care in shading and airing, no premature drying off, and also that the night temperature has not been allowed to drop too low. These conditions conduce to healthy foliage and vigorous spikes. We have Calanthes here (November 22) with flower spikes five feet long, and the foliage still quite fresh. They are C. Veitchii and C. bella. *T. B. Field, Wych Cross Place Gardens, Forest Row.*

Huge Surplus of Scottish Potatos.—Great perturbation is being felt in Potato-growing districts in Scotland at the miserable prices—computed at something like half the cost of production—now being offered to growers, and it is felt some effort must be made if Scottish growers are not to be mulcted in the loss of over a million pounds. Various remedies are suggested, the latest being by Mr. D. W. Innes, President of the Kincardine County Executive of the National Farmers' Union, who advocates in a circular he has sent out to growers the exportation to South American and Mediterranean ports of five per cent. of the surplus, equal to some 50,000 tons. Of course, this could only be done by the formation of a pool, as no individual grower could be expected to incur a loss for the benefit of his neighbours. Were this sacrifice made, there would, Mr. Innes contends, be an immediate improvement on home prices. This remains to be seen. Meantime, it may be interesting to note here the peculiarities of our Potato markets, and the trade in general. In past years, during seasons when the Potato crop turned out a good one, there must have been noted a loud hue and cry set up among the middlemen regarding the great difficulty they would have in handling so large a crop, and that they could only do so with safety by offering very low prices for their supplies. Many growers were stampeded by this talk and sold out at once to prevent the risk of what appeared to them an even further fall. Then, when the great bulk of the crop had been transferred to the merchants' hands, large quantities of which were pitted for convenience on the growers' fields, there came slowly and mysteriously a big rise in prices, so one can easily picture the chagrin of a grower seeing his crop carted from the pits in his fields and knowing they were being sold at twice and even three times the price he had been paid for them. Even as it is, with prices for ware commanding little over 30s. per ton, let anyone go into a retail shop and ask for a stone of Potatos. It will be found that for the fourteen pounds weight of Potatos 6½d. at the lowest will be charged. This works out at £4 6s. 8d. per ton, and in districts, too, where Potato growing is carried out on a large scale. Somebody is making a good thing out of all this, even when transport and other charges are allowed on a generous scale. It is certainly not the unfortunate grower, for he, poor man, has the dice loaded against him from every point of view.—*Aberdonensis.*

GARDEN MANURES FOR DECEMBER.

In open weather, when ground operations may be carried out satisfactorily, the use of bulky, organic manure for incorporation with the soil in preparing it for future crops will probably be of the greatest importance from the manurial point of view during the present month. In this connection it may be noted that from the records of many manurial trials held in recent years there is considerable evidence to show that very heavy dressings of farmyard and similar manure are not desirable.

Generally, it may be stated that an application at the rate of fifteen tons per acre is sufficient for all ordinary purposes, and in one series of experiments where dressings of respectively fifteen tons and thirty tons per acre were allocated to adjoining plots there was no appreciable difference in the crops recorded. Moreover, an excessive supply of farmyard manure tends to favour soft growth which fails to produce normal crops, and is susceptible to the attacks of diseases, whereas all-round manuring produces sturdy plants resistant to attacks of disease and with a normal balance between their vegetative and reproductive parts.

There can be little doubt that a moderate application of bulky manure, supplemented by dressings of artificial fertilisers in the following spring and during the period of active growth, constitutes a practicable system of manuring which enables the grower to supply the various nutritive needs of the plant on the most economic basis.

It has been frequently pointed out that the physical factors of the plants' environment are at least as important as the manurial requirements, and thoroughness in soil preparation cannot be over emphasised. Not only will the greatest advantage accrue from the present application of organic manure, when its thorough incorporation with the soil is practised, but subsequent applications of artificial fertilisers will also be assisted to exercise their full benefit from this thorough cultivation. Apart from the fact that physical cultivation makes easy the incorporation of manures with the soil, without which much of their value may be lost, it always induces root action, and it is obvious that the greater the root surface and the more uniformly widespread the manurial agents, the more chance the plant has of absorbing available nutriment.

It may be stated that so much has been written on liming in recent years that there is no further need to extol its benefits, but in garden practice the present season is frequently a convenient one for the application of this important element, and a few notes on its uses may not be out of place. Not only is lime a useful manure in itself, but by its action in the soil it renders other plant foods more available. It is particularly useful on heavy, clayey soils, rendering them more friable and, on the other hand, it helps to make light soils more compact; it helps to decompose the organic matter in soils, it corrects sourness, releases potash, and hastens the processes of nitrification, while in soils well supplied with lime the dreaded finger and toe disease rarely, if ever, occurs.

A sufficiency of lime in our soils is, therefore, of paramount importance, and the increased use of chemical manures during recent years tends to increase the normal loss of calcium carbonate which occurs in soils, hence greater applications are needed to cover this loss.

Lime can be supplied to the soil in many ways. It has been already pointed out that such manures as basic slag and cyanamide contain a considerable proportion of lime, but not in sufficient quantity to maintain permanently the lime content of the soil. Gypsum is a natural form in which lime is found, its particularly valuable property being its power to retain ammonia. Shell sand, obtained from certain parts of the sea coast, contains a large proportion of lime, and is a valuable manure for nearly all classes of soils. It is sometimes supplied as lump lime, and slaked on the ground to reduce it to a sowable condition as slaked lime, but uniform distribution is not easy by this method, and by its caustic action it destroys organic matter in the soil; it is thus not wise to apply it to soils of low organic content.

For general garden purposes probably ground chalk or ground limestone are the most convenient forms in which to apply lime, and finely-ground samples applied at the present time may be expected to give results during the next season of growth. Lime has a tendency to sink rapidly into the soil and subsoil, and should therefore be applied to the surface after cultivating operations have been completed. Newly drained or reclaimed soils generally need liming, but many of our soils under intensive cultivation become deficient in lime unless moderate dressings are given every third or fourth year.

On newly reclaimed land which is pest-infested, it may be advantageous to apply fresh gas-lime, if this can be applied immediately so that its impturities become dissipated before the land is to be cropped. It contains sulphur compounds which are injurious to plant life as well as to the animal life of the soil, but when these have dispersed the residual lime acts as a fertiliser and re-agent in the same way as pure lime. *W. Auton.*

RATING RELIEF.

As our advice to a correspondent (see *Gard. Chron.*, November 9, p. 375) has been questioned, we publish the following extended information:—

The authority for our reply is the Local Government Act 1929 which amends and extends the provisions for rating relief contained in the Rating and Valuation (apportionment) Act 1928. Section 72 of the Local Government Act 1929 provides that the gross value of an agricultural dwelling-house shall be ascertained on the basis of its letting value as such and not on the basis of its letting value as an ordinary dwelling-house. In order to come within this section—

1. The house must be occupied in connection with agricultural land (which is defined in Section 2 of the Rating and Valuation (Apportionment) Act 1928).
2. The house must be used as a dwelling-house
    (a) by a person who is primarily engaged in carrying on agricultural operations on that land; or
    (b) by a person who is employed in agricultural operations on that land in the service of the occupier thereof, and is entitled, whether as tenant or otherwise, to use the house only while so employed.

The date of operation of this Section is April 1, 1930.

There are no fewer than five Acts of Parliament dealing with this question of Rating Relief and as in some cases several Acts have to be read together, it was considered to be less confusing to our correspondent to consolidate the numerous provisions of the relevant Acts in the general form of the reply.

The Rating and Valuation (Apportionment) Act 1928 provided that the valuation lists under which the new rating relief was to be given should come into force after October 1, 1929, but this date was subsequently altered to April 1, 1929, by the Agricultural Rates Act 1929. For some reason, however, the provisions of Section 72 of the Local Government Act 1929 do not come into force until April 1, 1930.

In view of the amount of correspondence received, which shows that many people are under the impression that the Act relates to this year's assessments, we may point out that they will not be entitled to the benefit of the Act until April 1 next.

SOCIETIES.

DEVON AND EXETER HORTICULTURAL.

This Society's show, revived after a lapse of fourteen years, was held in the Civic Hall, Exeter, on November 14 and 15. It is interesting to note that this Society was inaugurated just a hundred years ago. The number of exhibits, especially in the group and cut flower classes, was disappointing; but this was probably due to the diffidence which people sometimes have of exhibiting for the first time, or after a lapse of years. One can only hope that next year the schedule will be revised to enable others than subscribers to compete. The Apple and vegetable classes were more satisfactory, and were well filled, being quite up to pre-war standard. Pears were good, but not very numerous.

The Silver Cup presented by Miss E. V. Wills, of Haytor, for the best exhibit in classes 4, 5 and 6, was secured by Colonel H. Spencer Follett, C.B.E. (gr. Mr. M. S. Ashmead), with well-grown examples of Begonia Gloire de Lorraine. Mr. Willoughby S. Smith (gr. Mr. C. Coutts) won Sir Trehawke Kekewich's prize for the best exhibit in the Apple classes, with a very fine dish of Cox's Orange Pippin, and a prize by the same donor for Pears went to the Misses Mackinnon (gr. Mr. R. C. Baker), for a very fine dish of Doyenné du Comice. The President's prize, for the best exhibit of Chrysanthemums in the Amateur classes, was awarded to Mr. W. J. Nix, while the Silver Cup given by Messrs. W. Braford and Son, Ltd., Exeter, for the best basket of autumn foliage and berries, arranged for effect, was won by Mrs. N. R. Radcliffe, with a delightful arrangement.

The Silver Trophy presented by the late P. C. M. Veitch, Esq., J.P., V.M.H., for a collection of eighteen varieties of Apples, nine dessert and nine culinary, was won by E. Flamank, Esq., (gr. Mr. W. Collins), and the Cup presented by Sir Edgar S. Plummer, for a collection of vegetables, was won by the Misses Mackinnon (gr. Mr. R. C. Baker). There was only one entry for six Tree or Winter-flowering Carnations, distinct, and the Misses Mackinnon were awarded the first prize for well-grown plants of the varieties Cameron, Laddie, Malcolm, Topsy, Coral Glow and Sunset. In the class for four fibrous-rooted Begonias, Colonel H. Spencer Follett led easily with fine examples of Begonia Gloire de Lorraine, and was also first for six flowering plants, Chrysanthemums excluded.

For a circular group of Chrysanthemums in pots, J. W. Hussey, Esq. (gr. Mr. F. Woolacott) was the only competitor and was awarded the second prize, while in the class for six Single Chrysanthemums, on single stems, in pots, J. W. Hussey, Esq., was first.

The Misses Mackinnon were first for twelve Japanese Chrysanthemums, not fewer than six varieties, with excellent blooms of Mrs. B. Carpenter, Victory, Majestic, Queen Mary, R. C. Pulling, Birmingham and Yellow Majestic, Colonel A. D. Acland (gr. Mr. R. Habgood) being placed second. In the class for six distinct varieties, the Misses Mackinnon were again to the fore, with magnificent blooms of Majestic, Mrs. B. Carpenter, Aquitania, Queen Mary, Yellow Majestic and Scythia; and Colonel Acland was again second. In the class for six Incurved Chrysanthemums, J. W. Hussey, Esq., was first; and for six vases of Single Chrysanthemums, distinct, disbudded, Colonel H. Spencer Follett led, with fine blooms of Miss Joyce Moore, Golden Seal, Bronze Molly, Susan, Molly Godfrey and Red Molly. The Misses Mackinnon were second, their best vases being of Bronze Molly, Miss Joyce Moore, Cleopatra and R. Collins.

The Misses Mackinnon were first for six varieties of Single Chrysanthemums, not disbudded; while the first prize for any other variety of Chrysanthemum, was won by J. W. Hussey, Esq., Colonel Follett being second.

In the fruit section there was only one entry in the Grape classes, and the first prize was awarded to Colonel Follett for a creditable exhibit of Alicante. The first prize and Silver Trophy for a collection of eighteen varieties of Apples, was won by E. Flamank, Esq. (gr. Mr. W. Collins), with splendid dishes of Warner's King, Tower of Glamis, Mére de Mènage, Bramley's Seedling, Peasgood's Nonesuch, Bismarck, Lane's Prince Albert, Beauty of Kent, Lord Stradbroke, Adams's Pearmain, Lord Hindlip, Cox's Orange Pippin, Blenheim Pippin, Allington Pippin, American Mother, King of the Pippins, Charles Ross and Rival; second, Sir F. W. Acland (gr. Mr. E. Collins), his best dishes being of Bramley's Seedling, Annie Elizabeth, Tower of Glamis, Newton Wonder, Cox's Orange Pippin, Blenheim Pippin, William Crump, Adams's Pearmain and Charles Ross.

For a collection of six distinct dessert Apples, E. Flamank, Esq., was again successful, with well-coloured fruits of Adams's Pearmain, Allington Pippin, Charles Ross, Cox's Orange Pippin, Blenheim Pippin and King of the Pippins; second place being taken by Willoughby S. Smith, Esq., with good dishes of Adams's Pearmain, Barnack Beauty, King's Acre Pippin, Cornish Gilliflower, Cox's Orange Pippin and Charles Ross. In the corresponding class for culinary Apples, E. Flamank, Esq., again led the way, with Bramley's Seedling, Tower of Glamis, Stone's Pippin, Beauty of Kent, Peasgood's Nonesuch and Mére de Mènage; with Mrs. H. E. Tracy (gr. Mr. Rousley), a close second.

The single dish classes for Apples were well contested. Willoughby S. Smith, Esq., led for Cox's Orange Pippin and Cornish Gilliflower; but E. Flamank, Esq., was the leading exhibitor, securing first prizes for Blenheim Pippin, Peasgood's Nonesuch, Adams's Pearmain, King of the Pippins, Lane's Prince Albert, Bramley's Seedling, Gascoyne's Scarlet, Charles Ross, Newton Wonder and Allington Pippin; he also showed the first prize collection of dessert Pears.

The Misses Mackinnon were first for Glou Morceau in the single dish Pear classes; also for Josephine de Malines, Uvedale's St. Germain and Catillac. Colonel Follett led for Marie Louise; the Rev. W. G. Munk showed the best Pitmaston Duchess, and Mrs. H. E. Tracy was first for Winter Nelis.

The first prize and Silver Trophy for a collection of eight varieties of vegetables was won by the Misses Mackinnon. There were numerous other classes for vegetables, all of which were well filled, and there were conspicuous exhibits of Parsnips, Onions, Potatos and Cauliflowers.

In the classes for cottagers, artisans and allotment holders there was keen competition, and excellent produce was shown.

Trade exhibits contributed to the attractiveness of the show. Messrs. R. Veitch and Son, Exeter, set up a delightful group of Single Chrysanthemums, berried shrubs, Apples and Carnations.

Messrs. Jarman and Co., Chard, showed Chrysanthemums and Apples; Messrs. R. J. Case set up a splendid arrangement of Decorative Chrysanthemums; and Messrs. A. W. Hickley had a meritorious exhibit of Decorative, Single and Pompon Chrysanthemums. Certificates of Merit were awarded to all these trade exhibits, and also to E. J. Marden, Esq., J.P., for a splendid collection of Apples.

LANCASTER CHRYSANTHEMUM.

On November 16, this Society held its twelfth show, this being the sixth since its revival, in the Ashton Hall, and the exhibition was certainly a success.

The show was remarkable for the fact that local apprentice exhibitors have now become such craftsmen that they took all the leading prizes, particularly Mr. S. Carney and Mr. S. B. Carter. The former secured two Cups among thirteen first prizes, and the latter many firsts, including the Lord Ashton Cup. Mr. F. Smith, usually the leader, was handicapped by being about ten days ahead with his blooms, although his Japanese Chrysanthemum R. C. Pulling was the best bloom in the show.

Mr. S. Carney showed the premier bloom in the class for exhibitors employing no regular assistance, with Queen Mary.

The trophy winners were :—The Lady Storey Rose Bowl, for twelve Japanese blooms, Mr. F. Smith ; the Lord Ashton Cup, for a group, Mr. S. B. Carter ; the Alderman Jackson Cup, for the most points in section A, Mr. S. Carney ; the Councillor J. G. Clark Cup, for three plants of Japanese Chrysanthemums, Mr. S. Carney ; the Mrs. Musgrave Hoyle Cup, for a table of Single Chrysanthemums, Mrs. Pickard ; and the Miss Foster Cup, for a table of Decorative Chrysanthemums, Mrs. J. H. Massey.

In the open cut bloom classes some superb blooms were shown, and Mr. S. Carney secured the premier awards for twelve, six, three white, and three yellow Japanese blooms, with specimens in perfect condition ; and Messrs. F. Smith, S. B. Carter, E. Boardley and R. E. Coles (Barrow) interchanged places in these classes for second and third places. Mr. F. Smith led in the classes for three distinct Japanese blooms, nine, and a single Japanese. In the classes for Singles, Messrs. Carney and Smith shared the premier awards. Mr. Carney and Mr. Carter were the chief prize-winners in the classes for specimen plants.

In the other sections, some splendid blooms were shown, both Single and Japanese. The leading exhibitors were Mrs. Emmott and Messrs. E. Boardley, W. Smith, S. Winder, S. Carney, G. B. Parnell and W. Pinch.

Mrs. Emmott took first prizes for table decorations, an epergne and a bouquet ; and Mrs. Croft showed the best bowl of Decorative sorts.

The fruits and vegetables were very good. Miss Brighouse, Winmarleigh, secured the Alderman Curwen Cup with the most points for vegetables ; and Mr. W. Robinson, Forton, excelled with his collection of vegetables, and also secured many awards for his fruits. Other first prize winners were Councillor Mrs. Helme, Alderman Roberts and Messrs. T. Cook, T. Cole, I. Winder, R. C. Brighouse, J. Wilson and E. Hewitt.

IRIS SOCIETY.

The Annual Meeting of the Iris Society was held at the Grosvenor Hotel, London, S.W., on Wednesday, November 20, Sir William Lawrence, Bart., occupying the President's chair.

The Hon. Secretary, in his report, commented on the steady progress of the Society, both in membership and in the increase of its activities. The 1929 show, held on June 6 and 7, proved a great success, the attendance being much larger than at any previous show, and the number of exhibits showed a large increase of that of 1928. He expressed the gratitude of the Society to Mr. G. N. Bunyard for his research work on Iris diseases ; to Mr. George Dillistone, for organising the annual show ; and to Mr. P. R. Barr, for undertaking, and bringing so near completion, the arduous task of compiling a check list of Iris names. He also announced that the Society would in future publish a Year Book in July, instead of a Bulletin but that there would be special information leaflets circulated from time to time dealing with important matters regarding Iris culture.

The Hon. Treasurer presented his balance sheet, and stated that despite the heavy (and in some cases not recurring) expenses incurred during the year, the Society maintained a satisfactory balance in hand. Both reports were adopted.

The President then announced that at a previous Committee meeting, it had been decided to recommend the award of the Foster Memorial Plaque to Mr. G. L. Pilkington, for his enthusiastic and onerous work on behalf of the genus, and for his indefatigable efforts on behalf of the Society. Mr. Pilkington therefore becomes the second English recipient of this honour, and joins a small select band consisting of himself, Mr. George Yeld and Mr. J. C. Wister (United States of America), and Mons. S. Mottet (France). The meeting received the announcement with enthusiastic applause.

The Dykes Memorial Medal for 1930 (for the best seedling Iris) was awarded to "Joyance," a new seedling raised by Mrs. Dykes. Thus the first award of this Medal, in England, for a bearded Iris, goes in recognition of the foundation of a new series of seedlings laid by the man in whose honour and memory the medal was instituted, although in this case it represents the actual work of Mrs. Dykes, who continues her late husband's work.

Mr. George Dillistone was then asked to report progress with regard to the publication of the writings of the late Mr. W. R. Dykes. He stated these were now ready for the press, and submitted a specimen of the binding, paper and type it was proposed to use. The book he said, would make an excellent companion to the *Handbook of Garden Irises*, being about the same size (approximately 280 pages). It could be produced for sale at about 10s. 6d. or 12s. 6d., and he thought it would prove to be the most useful and interesting book on the genus hitherto published. It would appeal particularly to the amateur grower. This view was emphasised by Mr. George Yeld, who had assisted in the revision of the MS., and by Mr. G. P. Baker. who had made himself responsible for collecting many of the articles and also for obtaining guarantees for the cost of production. Mr. Dillistone was therefore instructed to proceed with all speed in the publication of the book, which he thought could be produced early in the New Year.

Mr. P. R. Barr reported that he had now completed his undertaking to compile a check list of Iris names, and submitted the list for inspection, and it was decided to proceed with its publication so soon as possible.

The Officers elected for the ensuing year were :—President, Sir William Lawrence, Bart. ; Hon. Secretary, Mr. G. L. Pilkington, Lower Lee, Woolton, nr. Liverpool ; Hon. Treasurer, Major George Churcher ; Hon. Editor, Mr. George Dillistone, 50, Claremont Road, Tunbridge Wells ; Hon. Auditor, Mr. L. Caldcott ; the Executive and Special Committees were re-elected *en bloc*.

After the meeting, the members present dined together, and some lingered discussing their favourite topic until after midnight.

CORBRIDGE-ON-TYNE CHRYSANTHEMUM.

The twenty-sixth Annual Exhibition of the Corbridge and District Gardeners' Chrysanthemum Society was held in the Town Hall, Corbridge, on November 16. This show again proved a great attraction and was well patronised. The Cottage Hospital, to whose funds the proceeds are mainly devoted, should benefit considerably thereby.

The Chrysanthemum blooms in all the classes were of exceptional merit, especially so in the Single, disbudded classes, and were probably the finest ever seen in this district.

In the class for four vases of Japanese, four varieties, J. C. Straker, Esq. (gr. Mr. A. Hay), Stagshaw House, was first, showing exceptionally fine blooms of Mrs. R. C. Pulling, Mrs. A. Davis, Miss F. Jolliffe and Mrs. H. Wells. The Dowager Lady Allendale (gr. Mr. J. Thomas), Bywell Hall, was second, with finely finished blooms of Majestic, Mrs. A. Davis, R. C. Pulling and Miss F. Jolliffe. In the class for six Japanese blooms, two varieties, Mr. Straker was first, with Algernon Davis and Red Majestic, and the Dowager Lady Allendale, second, with Red Majestic and Mrs. J. Gibson. For three Japanese Chrysanthemums in not fewer than two varieties, J. C. Straker, Esq., was again first.

In the class for three white Japanese blooms, A. Dove, Esq. (gr. Mr. L. Sharp), Riding Mill, led with good blooms of Mrs. H. Wells ; for three yellow Japanese, J. C. Straker, Esq., was first, showing R. C. Pulling, and also for three pink Japanese blooms with Algernon Davis ; while in the class for three bronze Japanese blooms, first place was taken by the Dowager Lady Allendale, showing Majestic in grand form. For three crimson Japanese blooms, first prize went to J. C. Straker, Esq., who showed lovely flowers of Mrs. G. Monro.

In the class for Incurved varieties, the Dowager Lady Allendale led, with J. C. Straker, Esq., second ; while for two vases Single Chrysanthemums, disbudded, J. C. Straker. Esq., was again successful, with grand flowers of Susan, Miss M. Thorn, Hilda Shoebridge and Supreme ; J. Straker Smith (gr. Mr. J. Winder), Howden Dene, was second. Lord Allendale (gr. Mr. A. Merrington), Dilston Castle, was first for two vases of Decorative kinds ; the Dowager Lady Allendale, second ; J. Straker Smith, Esq., third. The remaining classes for Decorative and Single varieties were well filled and some very fine specimen plants were also exhibited. One of the great features of the show was the very fine collections of Carnations from Lord Allendale and Mr. J. C. Straker.

In the fruit classes, Apples were the chief attraction. For nine dishes of Apples J. A. Baty, Esq. (gr. Mr. T. Denwoddie) was first, showing good dishes of Warner's King, Lord Derby, Bramley's Seedling, Laxton's Supreme, Charles Ross, James Grieve, Worcester Pearmain and Ribston Pippin ; J. C. Straker, Esq., was second. For four dishes of Apples, two dessert and two cooking kinds, J. A. Baty, Esq., again led, showing Cox's Pomona, Lord Derby. James Grieve and Worcester Pearmain. J. Straker Smith, Esq., was second. There were but two competitors in the Grape class, J. C. Straker, Esq., winning with finely finished bunches of Black Alicante.

The vegetable classes were well contested. Leeks especially being extensively represented.

CARDIFF GARDENERS'.

The fortnightly meeting held in the Queen's Hotel, on November 26, was presided over by Mr. W. H. Pryce. As this was "Question Night," there was a good attendance, as many members have an opportunity to air their views, and get difficulties solved. Probably some of the most interesting questions asked and answered were on Chrysanthemums, Dahlias, seed Potatos, pruning shrubs, the use of Volke, white fly and Begonia mite, and the value of cordon Apple trees in the small garden. After a lengthy discussion, it was unanimously decided that Laxton's Progress was the best dwarf Pea.

An excellent exhibition of three dishes of Apples was staged, and the first prize was awarded to Mr. W. Clarke ; second, Mr. J. Jones ; third, Mr. T. Kirby. There was also a good show of Decorative Chrysanthemums, and prizes were won by Mr. J. Jones, Mr. A. Cassom, and Mr. T. Thorburn. Points were also awarded to Mr. J. Jones for a magnificent dish of Doyenné du Comice Pears ; to Mr. H. Jenkins for Apples ; Mr. Baker for Chrysanthemums ; and Mr. Kirby for Pears.

Towards the close of the meeting reference was made to the recent successes of several members, and the fine result of the Llanishen and Lisvane Chrysanthemum Society's first show.

ROYAL BOTANICAL AND HORTICULTURAL OF MANCHESTER.

The Autumn Show of this Society, held in the Town Hall, Manchester, on November 12 and 13, was a great success. All the competitive classes were well filled, and the trade was well represented. The general management of the show was excellent.

The show is primarily for Chrysanthemums, and these were the chief feature. Messrs. W. J. Garner and Sons, Altrincham, were first in the large group class, and were also awarded a Gold Medal. Mr. H. Woolman exhibited a very fine lot of blooms which won the *Manchester Guardian* Challenge Cup ; and Messrs. Keith Luxford and Co. were awarded a Gold Medal, as also were Messrs. Dickson and Robinson. In the big Orchid class, Mr. John Evans. Colwyn Bay, secured the first prize and *Daily Dispatch* Challenge Cup, staging a very fine exhibit.

The Manchester Parks Department displayed a fine exhibit of Palms, Ferns and Chrysanthemums, which formed a fine setting to the large platform. Perhaps the most interesting and educational exhibit came from the Cheadle Royal Mental Hospital gardens, for Mr. A. Falconer staged well over one hundred dishes of choice vegetables. This exhibit was awarded a Large Gold Medal, and included Peas, Beans, Cauliflowers, Capsicums, Celery, Cardoons, and many of the more uncommon vegetables.

NEWCASTLE-ON-TYNE HORTICULTURAL.

The Newcastle-on-Tyne Horticultural Society held its annual show in the Royal Engineers' Hall, on November 20 and 21. There was a record number of entries, the quality of the blooms, pot plants, Leeks and collections of vegetables altogether surpassed last year's excellent exhibits.

J. C. Straker, Esq. (gr. Mr. A. Hay), Stagshaw House, Corbridge, won the W. F. Henderson Cup, with twelve Japanese Chrysanthemum blooms, and also the Cup given for the most meritorious exhibit in the show. The Lord Ravensworth Cup, for a collection of vegetables, was won for the second year in succession by Mr. Thomas Etty, Heddon-on-the-Wall; the W. F. Henderson Cup, for six Japanese Chrysanthemum blooms, confined to members of the Society, was awarded to J. C. Straker, Esq., and the Townend Cup, for a miniature rock garden, was won for the third time in succession by Mr. J. Kirkbridge, Foresthall, and now becomes his own property.

Specimen Chrysanthemum plants were a very strong feature, and Mr. J. B. Smith, Fawdon Nurseries, Gosforth, showed especially fine plants of Blanche Poitevene, one with one-hundred-and-twenty-two blooms and another with ninety-four perfect blooms.

The winner in the table decoration class was Mr. J. B. Smith, who had an artistic arrangement of pink Single Chrysanthemum Flora; there were seven competitors, the second prize going to Miss Lang, Monkseaton. The first prize for pot Leeks, always a strong class in the north-east, was carried off by Mr. J. W. Oliver, Fourstones.

The Dowager Viscountess Allendale (gr. Mr. J. Thomas), Bywell Hall; Lord Ridley (gr. Mr. T. Mytton), Blagdon Hall; and S. Harrison Smith, Esq. (gr. Mr. T. J. Davidson), were among the successful exhibitors in the fruit and cut bloom sections.

The amateur classes were well filled. A Gold Medal, given by Messrs. J. B. Smith and Co., Fawdon Nurseries, for the most meritorious exhibit, was won by Mr. J. S. Charlton, Gateshead.

The honorary exhibitors included Messrs. S. Finney and Co., who had bulbs, sundries, etc.; Messrs. J. B. Smith and Co., Chrysanthemums; Messrs. C. J. Dillon, shrubs, Rose plants and an ornamental garden; Messrs. S. Thomson, a group of miscellaneous plants and rustic arches; the Parks Department, a group of Begonia Gloire de Lorraine; Mr. George Lee, large specimen Palms and Bay trees; Messrs. J. S. Patterson and Sons, stone garden ornaments; and Messrs. T. Fairbairn and Sons, a group of the winter-flowering Begonia Elatior.

GUILDFORD GARDENERS.'

The Annual Meeting was held on Tuesday, November 19, and there was a good attendance of members, many of whom had come from distances up to twelve miles.

The President, Mr. W. T. Patrick, J.P., in presenting the comprehensive Report of the Committee, and Statement of Accounts, said he felt any association might be very proud of it. The report showed continued progress, not only in membership and finance, but in work done.

He ventured to suggest that the claims of the committee that the Association was one of the strongest in the south of England were amply justified. The Association was doing a great deal to give people the opportunity of learning more about horticulture. What better recreation and relief from the worries of business could they find than working among the flowers of which they were so fond? The Association's work was of considerable educational and social value to Guildford and the neighbourhood. He had been to the trouble of trying to discover an association so strong as theirs in the south of England, but had not found one with a report such as they were issuing. They needed members to act as missionaries to secure honorary members and vice-presidents. It was gratifying to see that there was a membership of 885, and that no subscription was owing. That state of affairs was largely due to the energy displayed by Mr. Childs.

Cordial thanks were given to the press, with special mention of *The Gardeners' Chronicle*, by means of which the work of the Association is made known to a wider circle.

So far as the finances were concerned, it would be seen that the great event of the year, the Summer Show, was a heavy item, and did not clear expenses by £26. Also the monthly *Journal*, delivered free to all members, was a charge of £47 on the general funds; but the other sections—the outings, whist-drives and social activities—were satisfactory, in fact, the accounts were the most satisfactory since the formation of the Association. They were now fairly in the saddle, and the President did not see why they should not continue to progress. The credit balance last year was £66 7s. 11d., and this year it was £150 5s. 8d. The lectures and outings were very instructive, and the annual show maintained its high standard and popularity. Part of the Association's work was to educate the elementary school children in gardening, and they were indebted to the school-masters for their assistance.

Mr. Patrick asked that a new President should be appointed, but he was re-elected, tributes being paid to his services by Mr. A. J. Joy and Mr. W. F. Stedman. The other officers were elected as follow: Hon. Secretary, Mr. C. F. Childs; Hon. Secretary to Show Committee, Mr. P. Pettit; Committee: Messrs. F. Ansell, W. F. Binfield, A. Blake, J. H. Blunden, E. Hewett, A. Jakins, A. J. Joy, W. Long, J. Mackay, G. H. Mason, T. Newman and A. H. White.

A surprise item was a personal gift by the President to Mr. Nation and Mr. Stedman of four bound volumes of the monthly *Journal* as an expression of his appreciation of their services to the Association.

The winter programme began with a social gathering on the last day in October; Mr. A. E. Burgess gave a helpful and informing lecture on "Manures and Manuring" on November 12; and there was a whist drive on Wednesday, November 27. The next lecture is on "Rock Gardens," by Mr. J. Coutts, Assistant Curator of Kew Gardens, on Tuesday, December 10.

DERBYSHIRE HORTICULTURAL.

The twenty-second Chrysanthemum Show held at Derby early in November, under the auspices of the Derbyshire Horticultural Association, was undoubtedly the biggest step forward in the Chrysanthemum movement in the midland counties this year. Over 350 entries from seventy-five exhibitors so heavily taxed accommodation in the Royal Drill Hall, that the glass-covered annexe had to be requisitioned.

Messrs. Mansell and Hatcher staged a 200 square feet group of Orchids, including Cattleyas, Odontoglossums, Lycastes, Cypripediums, the interesting Bulbophyllum Lobbii var. siamense, and a good plant of Selenipedium longifolium var. Hartwegii, and were awarded a Large Gold Medal. At the other end of the hall, Messrs. Sutton and Sons exhibited 120 dishes of vegetables, comprising fine specimens of Capsicums, Celery, Leeks, Potatos, Onions, yellow and red Tomatos, Sugar Corn, ornamental Gourds, and dishes of most varieties of vegetables in general use, and for which they were also awarded a Large Gold Medal.

The centre of the hall was occupied by a miscellaneous group of exotic plants, 100 square feet, including Pandanus Veitchii, Codiaeums, Nandina domestica, Eulalias, Liliums, winter-flowering Begonias Gloire de Lorraine and Optima, surmounted by a large Kentia, and for this Mrs. Walter Evans (gr. Mr. J. Maxfield), Darley Abbey, was awarded the Silver Cup presented by H. T. Ann, Esq., Chairman.

Close to this were two groups kindly sent by A. Leslie Wright, Esq. (a Vice-President), (gr. Mr. J. Cartledge), Butterly Hall, which included Alocasia Lowii, Eulalias, Dracaenas, Nephrolepis todeaoides and Adiantums, as well as many varieties of Chrysanthemums; the same gentleman also decorated the platform with Kentias, Liliums and Chrysanthemums, and was awarded a Gold Medal.

Trade exhibits included displays from Mr. H. Woolman, Messrs. Dickson and Robinson, Messrs. Allwood Bros., Mr. C. Gregory, Messrs. William Lowe and Son; and alpines, Messrs. Dickinson, Mr. Stephen Sims, Messrs. J. M. Stewarts, Messrs. C. D. Cheesborough, and Mr. J. H. Coley.

The Captain Drury-Lowe Silver Cup for two dozen Japanese Chrysanthemums attracted five entries, and was won by Captain R. B. Brassey (gr. Mr. J. G. Quinn), Cottesbrook Hall, Northampton; second W. E. Ann, Esq. (gr. Mr. L. Dutton), Darley Field; third, Mrs. Walter Evans, Darley Abbey. The President's Cup, presented by J. A. Aiton, Esq., of Duffield Park, also went to Captain R. B. Brassey; second, Mr. H. H. Tomlinson, Derby; third, Mrs. Walter Evans. The G. H. Strutt Silver Cup, for a display of Single Chrysanthemums nine feet by three feet, was awarded to W. E. Ann, Esq.; second, Mrs. G. H. Strutt (gr. Mr. J. Middup), Belper; third, Mrs. Walter Evans; fourth, J. A. Aiton, Esq. (gr. Mr. J. H. Thomas). Messrs. J. Peed and Sons' (London) Silver Cup was won by W. E. Ann, Esq., Darley Fields; second, Mrs. Walter Evans, Darley Abbey: third, J. A. Aiton, Esq.

In the members' Classes, Mr. H. H. Tomlinson, Derby, won the C. W. Catt Cup, with twelve Japanese blooms arranged for effect; second, Mrs. Walter Evans; third, L. A. Clowes, Esq. (gr. Mr. J. Hammond), Norbury Hall. The Association's Silver Challenge Shield for twelve dishes of British-grown hardy fruits, went to Mrs. Walter Evans; second, J. Woodward, Esq., Draycott: third, W. E. Ann, Esq., Derby. The Silver Cup presented by Mrs. Bourne Wheeler this year in remembrance of her father, was won by Mrs. Walter Evans; second, Captain Brassey; third, Sir William Bass (gr. Mr. J. E. House), Burton-on-Trent.

Messrs. With's (Hereford) Silver Cup was awarded to Mr. J. Woodward, for a collection of vegetables (nine kinds); second, Mrs. A. Moore, Alvaston; third, Mr. F. A. Burton, Derby.

The Silver Cup for a semi-circular group of Chrysanthemums, five feet by four-and-a-half feet (plants only), was won by C. S. Buck, Esq.; second, Mr. A. Moore; third, Mr. J. Potter. The W. E. Watt Silver Cup offered to artisan members, for six Japanese blooms, was won by Mr. F. Meakin, the late Secretary; second, Mr. P. Spencer, Belper; third, Mr. J. Brown, Kilburn. The Derby *Daily Telegraph* Cup for a collection of vegetables (six kinds), was won by Mr. A. Moore; second, Mr. J. B. Jessop, Belper; third, Mr. J. W. Fulcher, Draycott.

The new provincial class provided by the National Chrysanthemum Society for twelve Japanese blooms, distinct varieties, secured a good competition, and Captain R. B. Brassey, Northampton, won the first prize and Silver Medal; second, and Bronze Medal, Mr. H. H. Tomlinson, Derby. The premier bloom in the open classes, carrying the N.C.S. Certificate, was won by Captain R. B. Brassey, with a fine specimen of Majestic; while in the artisan classes, Mr. F. Meakin was successful with a grand bloom of Mrs. Gilbert Drabble.

Over 12,000 people paid for admission to the show, and the Derby Education Committee ran special cars for the school children, about one thousand of whom evinced a keen interest that was very pleasing.

The opening ceremony was performed by Mrs. Bourne Wheeler, of Netherlea Hall, Holbrook, to whom a bouquet of Carnations was presented by Miss Lawsley. The secretarial duties were carried out by Mr. W. Wardman, 5, St. Augustine Street, Derby.

WIMBLEDON GARDENERS'.

The eleventh annual exhibition of the Wimbledon and District Gardeners' Mutual Improvement Society was held in The Drill Hall, St. George's Road, Wimbledon. The exhibition was opened by Percy Mortimer, Esq., J.P., who spoke feelingly of the absence of Sir Joseph Hood, Bart., J.P., through illnesss. Among those present were Her Grace The Duchess of Buckingham and Chandos, Lady Hood, Lady Power, Lady Holland, The Mayor and Mayoress, Sir James Caird, Bart., J.P., T. C. Summerhays, Esq., J.P., A. Hosking, Esq., Chairman of the

Society, and Mr. W. G. Wood, Hon. Secretary and Treasurer.

The show was a very large and varied one, consisting of 309 entries—thirty-six more than that of the previous year. Mr. W. Hunt was superintendent of the show, and was very ably assisted by the members of the Committee.

In the evening the hall was packed by an admiring crowd, which made it a difficult task to pass round and view the splendid array of flowers, vegetables and fruits, as well as jams, jellies, bottled fruits, marmalade, cakes, bread and cooked Potatos.

Mr. Frank Moon was the chief prize-winner, taking the George Roberts Silver Challenge Bowl, the Silver Bunyard Medal, the Silver Toogood Medal, as well as a large number of other prizes. As he won the Bronze Banksian Medal in 1928, this passed to Mr. K. Norrie. Mr. W. E. S. Debenham Cook won the Gold Medal presented by Major T. Lethaby for the premier bloom. Mr. F. J. Chapman retained the Silver Cup in the amateurs' and Cottagers' section.

Mr. E. Abraham held a guessing competition with a box of Apples, the prize winner being Mr. Henry Young; and Mr. J. Lyne disposed of a large quantity of fruit at the conclusion, the resulting sums of money benefiting the Royal Gardeners' Orphan Fund and the local hospitals. In the opinions of many present, this was the best show the Society has ever held.

NATIONAL CHRYSANTHEMUM.

Notwithstanding the dismal weather, there was a good attendance at this meeting of the Society's Floral Committee, held at the R.H.S. Hall on December 2, when a dozen novelties were presented and the following awards made :—

First Class Certificates.

Kenneth Hastie. II. 1*b*.—A very bright, rich crimson Decorative variety, with golden tips and dull old gold reverse to the central florets. Shown by Mr. H. Shoesmith, Junr.

Mrs. A. H. Boaden.—*I.* 2.—A rather small but very attractive Incurved variety of soft golden-yellow colour. Shown by Messrs. H. J. Jones, Ltd.

Golden Balcombe. II. 1*b*.—A useful late-flowering, golden-yellow Decorative variety, with firm, fairly broad florets. Shown by Mr. T. Stevenson, Hillingdon.

Gladys Pierson. II. 2.*a*.—In this loosely Incurved-Japanese form the flowers are large and the colour a pleasing shade of golden-buff. Shown by Messrs. Keith Luxford and Co.

Balcombe Bronze.—A highly decorative variety of very pleasing form; the colour is deep bronze, with gold tips to the inner florets. Shown by Mr. A. G. Vinten.

EDINBURGH CHRYSANTHEMUM SHOW.

A second-year effort to resuscitate the Edinburgh Chrysanthemum Show was much more successful that the first. Although not promoted by the Royal Caledonian Horticultural Society, the three days' exhibition, which was opened on November 21, in the Drill Hall, was under its patronage, and there is a possibility that the Directors will favourably consider in the near future a proposal to take over its future management.

On this occasion the entries in the three sections—Chrysanthemums, fruits and other flowers—numbered approximately three hundred, and a healthy competition was experienced in several of the seventeen classes for Chrysanthemums.

In the class for six vases of Decorative varieties, disbudded, which carried with it the Millgrove Challenge Trophy, Mr. Robert Grant, Boness, defeated Mr. James C. Lyle, Inverkeithing, the winner's best blooms being Cranfordia, In Memoriam, Lady Brunton and Hopetoun Beauty.

The trophy presented in the class for six vases of Decorative blooms, not disbudded, was won by Mr. R. McKenzie, Dochfour Gardens, Inverness, who staged specimens of Emily, Johnstone, Almirante, Jean Pattison and Pax in fine condition. He was also first for four vases of Decorative, disbudded, and for three Japanese blooms.

Mr. G. Wilson, Gogarburn Gardens, Corstorphine, was a strong candidate for the Cup presented in the class for four vases of disbudded Singles, which he won with a first-class quartette composed of Susan, Bronze Mollie, Joyce Moore and Phyllis Cooper, and he also excelled in three other classes, viz., for two vases of Decorative, disbudded; three vases of Decorative, not disbudded; and nine Japanese blooms.

Considerable interest centred in the competition for eighteen blooms of Japanese Chrysanthemums, the first prize winner in which was to be rewarded with a Challenge Trophy, commemorative Medal, and a cash prize. The blooms were staged singly in individual vases and made an imposing display. The winner was Mr. J. Loan, Coldstream, and the best flowers in his group were Francis Rowe, Red Majestic, Yellow Majestic, Mrs. George Monro and Majestic.

The classes for Single Chrysanthemums were well filled and the flowers were of superior quality generally. Mr. W. Lamb, Prestonfield, Craigmillar, gained first prizes in two classes, one disbudded and the other not disbudded, with outstanding examples of Phyllis Cooper and Ceddie Mason, while Mr. W. Swan, West House Gardens, Morningside, succeeded with four vases, containing not more than twelve sprays, which included unfinished specimens of Robert Andrews.

The decorative and pot plant sections were poorly represented. Here the first prize winners were Mr. A. S. Watt (one vase with any decoration); Mr. Alex. Cameron, Liberton (bouquet); Miss Grant, Boness (basket), and Mr. A. McKay (two pots Decorative and two pots of Single Chrysanthemums).

In the fruit section, Mr. J. Loan was first for four dishes of baking Apples, and for two dishes and one dish of dessert Apples.

Vegetable exhibits were numerous and of superior quality. Mr. A. C. Cameron won the Challenge Cup for the best display of vegetables with a collection numbering twenty-seven varieties, and Mr. J. Cochrane, Galashiels, had three first-class honours to his credit. The Medal for six varieties of Potatos was awarded to Mr. W. Redpath, Holylee, who also staged the best round, kidney and coloured Potatos; Mr. W. Lamb, Prestonfield, scored with six Leeks.

In the non-competitive section, Gold Medals were awarded to the City Parks Department for an imposing display of Chrysanthemums in pots; to Messrs. Dobbie and Co., for a comprehensive collection of cut blooms; and to Messrs. Wilson and Co., for a choice exhibit of Begonias and Cyclamens.

READING GARDENERS'.

There was a very large attendance of members at the fortnightly meeting held in the Abbey Hall on the evening of November 18 and presided over by the President, Mr. Frank E. Moring.

The subject for discussion was "The Propagation of Flowering Trees and Shrubs," and this was introduced in a most interesting talk by Mr. W. Martin, Victoria Nurseries, Reading. In his opening remarks, he said that the subject was one of the most fascinating branches of horticulture, and was of extreme importance, whether private or commercially. The lecturer suggested various methods of procedure with a few of the most popular kinds, and mentioned that there were several methods of propagation, by seeds, division of roots, cuttings, layering, budding and grafting. Practical details were given on each method.

A discussion followed, sustained by Messrs. Broomfield, Howlett, Lowe, Moulton, Waite, Clacy, Roberts and others. At the close Mr. F. Townsend proposed a hearty vote of thanks to Mr. Martin.

There were some magnificent specimens of Apples and Pears in the various competitions. In class 1, for three dishes of Apples, two culinary and one dessert, there were ten entries, the first prize going to Mr. H. Tuffin, Iris Court Gardens, Pangbourne; and the second to Mr. A. Manley, Highfield Park Gardens, Heckfield.

In the class for three dishes of Pears, three distinct varieties, there were nine entries. Mr. H. Tuffin was again first, and Mr. W. Turnham, Greenlands Gardens, Henley-on-Thames, second.

In class 3, confined to single-handed gardeners and amateurs, for a dish of Apples, there were five entries. Mr. C. J. Howlett, The Yews, Earley, was first, and Mr. A. E. Sharpe, Alexandra Road, Reading, second.

In the non-competitive section, Mr. C. J. Howlett staged several vases of Chrysanthemum blooms and three dishes of Lady Henniker Apples: while Mr. R. Turner, Southview, Calcot, showed a vase of seedling Single Chrysanthemums.

MAIDENHEAD CHRYSANTHEMUM.

The Maidenhead Chrysanthemum show was held in the Drill Hall in mid-November, and was a great success. The entries were many and the quality of the big blooms in the vase class excellent. These were best shown by Lady Finlay (gr. Mr. R. Evans), who won the first prize for the third year in succession, and so secured the Viscount Hamilton Cup; the N.C.S. Certificate was also awarded to Lady Finlay. Large blooms of Louisa Pockett were shown by Mrs. Hornby Lewis (gr. Mr. Friend), who came second; and Mrs. Thompson (gr. Mr. D. Barnard) was third.

The groups were very fine, and the premier award was won by Lady Vansittart Neale (gr. Mr. McCaul), who received the Mop Cedar Cup, which she has now won outright. Second, J. Bouton, Esq., Marlow (gr. Mr. Clark); third, E. C. Eastick, Esq. (gr. Mr. Hoyle).

Other classes were well filled, the Single Chrysanthemums, fruits and vegetables being excellent. Trade exhibits filled one end of the hall and were from Mr. Hatch, of Cookham, who was awarded a Gold Medal. Most of the prizes offered were given by the Maidenhead tradesmen, who always generously support the Society.

SHEFFIELD CHRYSANTHEMUM.

The Sheffield Chrysanthemum Society's forty-second Annual Exhibition, held in the R.F.A. Drill Hall, Sheffield, on November 14, 15 and 16, provided a grand display, for the blooms exhibited were quite up to standard, and were a great tribute to the skill of the Sheffield and district gardeners, who comprised ninety per cent. of the exhibitors. The entries were only ten short of the record 695 of last year, and this year's number of individual competitors constitutes a record.

A very interesting feature of the show was the artistic rock garden in Derbyshire tufa, complete with pool, exhibited by Mr. Stephen Sims, for which he received a Gold Medal. There were thirteen groups by members of the Society and six exhibits in the very interesting decorated fireplace class.

Mr. H. Woolman was awarded the first prize for a collection of Japanese blooms, and also received a Gold Medal for his grand group of Single Chrysanthemums. Messrs. Seagrave and Co. received a Gold Medal for their non-competitive exhibit of Chrysanthemums, and a Gold Medal was also awarded to Messrs. Sutton and Sons for a splendid collection of Potatos.

In the open classes for Chrysanthemums, Mr. W. Fletcher showed the best six vases of Single varieties; Mr. H. Woolman was first for eight vases of Japanese blooms, and for a display of Single Chrysanthemums, while Mr. G. Hopkinson, Sheffield, led for four vases of Japanese blooms, Messrs. H. Rutter and Sons for three blooms of a yellow variety, Mr. George Thomas for a pink or red Japanese Chrysanthemum, and also for three blooms of any other coloured variety.

Mr. E. Bagshaw, Chapel-en-le-Frith, showed the best eighteen Japanese blooms, any varieties; Mr. E. Fletcher was first for twelve Incurved blooms, and Mr. H. W. Walker, Sheffield, showed the best five vases of Single Chrysanthemums.

Other prize-winners in this section were Mr. J. W. Ambler, Sheffield, for six vases of Decorative blooms; and Mr. W. Fletcher, who was first for a vase of nine Japanese blooms, six vases of Singles, and six pot plants of Primulas, any varieties.

In the district classes the most prominent exhibitors were Mr. C. Fletcher, Mr. W. Tozer, Mr. W. Hyde, Mr. M. Croshin, Mr. W. Smith and Mr. C. Hinchcliffe.

The leading prize-winners among the amateurs were Mr. G. Hopkinson, Mr. W. W. Stiles, Mr. W. Smith, Mr. G. W. Amber and Mr. H. Furness, while in the cottagers' classes, the first prize winners were Mr. W. Furness (three), Mr. W. Marlow and Mr. E. Wragg. Mr. W. Furness was also successful in the novices' Chrysanthemum section, as also were Mr. J. W. Walker, Mr. A. Yeardley, Mr. G. Drury, Mr. C. E. Elliott, Mr. G. W. Hill and Mr. A. J. Beech.

The vegetable classes, both open and for amateurs, were well filled, and these proved an interesting feature of the show.

BARROW CHRYSANTHEMUM.

The ninth Annual Chrysanthemum Show of this Society was held on November 9, in the old Town Hall, when there was a capital show, and the entries were above the average.

Barrow is fortunate in having some stalwart Chrysanthemum exhibitors from pre-war days, and they are still in the front rank, and include Mr. Christian and Mr. Muddiman. The former was the principal prize winner in the open section, Mr. E. Oxley in the amateur section, and Mr. L. Jordon in the novices' section. Messrs. Hexham took first place for a trade exhibit, with Mr. Muddiman second; while Mrs. Benson, Grange-over-Sands, was first for a table decoration.

Other successful exhibitors were:—Captain J. Fisher (President), and Messrs. J. Clark, R. E. Cole, J. H. Farnham, H. Goldstraw, T. Holmes, R. F. Jones, J. McPherson, A. Nicholls, J. P. Smith, A. W. Thompson and F. T. Wilson.

Obituary.

W. Wesker.—An old and valued member of the Committee of the United Horticultural Benefit and Provident Society, Mr. W. Wesker, met his end with tragic suddenness on November 26. He was returning home early that morning when his bicycle skidded, he was knocked down by a passing motor-van and died without regaining consciousness. Mr. Wesker underwent a severe operation about two years ago, and since then had practically retired, although retaining his interest in all gardening matters and especially in allotment gardening in the Wandsworth and Tooting districts, In the early '80's Mr. Wesker was a successful exhibitor at the Regent's Park shows, and he also won many prizes for trained Chrysanthemums in the days when the National Chrysanthemum Society held exhibitions in the Royal Aquarium. For many years he was gardener to the Holloway family (contractors) and was literally a friend of the family. A robust, jolly man until his operation, Mr. Wesker's good spirits never failed under his severe illness. A very likable man, he was greatly loved by the Officers and Committee of the U.H.B.P., all of whom will sadly miss his cheery personality and his bluntly outspoken observations. The funeral took place at Streatham Cemetery on November 30, when many friends and representatives of the U.H.B.P. and the Tooting Brotherhood—of which he was a prominent member—paid tribute to the deep affection in which their friend was held.

ANSWERS TO CORRESPONDENTS.

Area for Fruit and Vegetable Garden.—*Auricula.*—Four acres of land should be sufficient to produce the quantities of fruits and vegetables required, but it is better to err on the side of having a larger area, than not sufficient to meet requirements. No hard and fast rule can be given as to weights, as in these days all vegetables should be served *ad lib*, and much depends on whether they are to be provided for growing school boys or elderly persons. The question of labour to grow the quantities stipulated depends on whether the ground is to be worked by hand, or with up-to-date implements and machinery. If the former, three men and a boy; if the latter two men, and a boy to collect the produce and deliver, but much depends on the man in charge as to his ability to get things done, and employing good experienced workmen. No head gardener worthy of the name should undertake Saturday and Sunday duties except under exceptional circumstances. The glasshouses enumerated could be managed by one man to produce the required crops, and he could also find time to keep paths tidy and assist in the vegetable and fruit garden. The mowing of four acres of lawn with a hand-machine in these days of cheap motor-mowers is false economy; the area stipulated being approximately one days work with a suitable machine. To sum the whole matter up, if the place is to be worked on up-to date lines, the head gardener, three men and a boy should meet the requirements, but much will depend upon their ability and general circumstances.

Names of Fruits.—*E. P.* 1, Yorkshire Beauty; 2, Bismark; 3, Winter Greening.—*G. W. G.* 1, badly decayed, not recognised; 2, Pitmaston Duchess; 3, Cellini; 4, Golden Noble; 6, Marguerite Marillat.—*E. S.* 1, Newton Wonder; 2, Dumelow's Seedling.—*Altho.* 1, Cox's Orange Pippin; 2, probably Benn's Red; 3, Blenheim Pippin.—*B. E. G. B.* 1, poor specimen, send again; 2, Warner's King; 3, Gold Medal; 4, Early Victoria; 5, 6 and 7, poor specimens, send again; 8, Belle Julie.—*C. W.* King of Tompkins County.—*Puzzled.* 1, Royal Late Cooking; 2, Endsleigh Beauty; 3, Winter Greening (?); 4, Royal Late Cooking; 5, Ribston Pippin; 6, Gravenstein; 7, Golden Noble; 8, The Queen; 9, Blenheim Pippin; 10, Duke of Devonshire; 11, Christie's Pippin; 12, Bramley's Seedling; 13, Lord Derby; 14, Royal Jubilee; 15, not recognised; 16, Yellow Ingestre; 17, Braddick's Nonpareil; 18, Hormead's Pearmain; 19, Lord Derby. *G. B.* 1, Baumann's Red Reinette; 2, possibly Hormead Pearmain; 3, poor specimen, not recognised; 4, Norfolk Beefing.—*A. C.* 1, poor specimen, possibly Bramley's Seedling; 2, Old Nonpareil; 3, Souvenir du Congrés.—*G. P. St. G.* Nouveau Poiteau.

Names of Plants.—*J. A. M.* Ruellia macrantha.—*J. S.* 1, Reineckia carnea; 2, Coronilla Emerus; 3, Duranta sp. probably D. glauca. D. Plumieri is commonly used as a hedge plant in India and in the east generally.—*J. C. G.* Cotoneaster frigida.—*Mona.* 1, Eriobotrya japonica (Loquat); 2, Daedalacanthus nervosus (Eranthemum pulchellum); 3, probably Begonia manicata; 4, Muehlenbeckia complexa; 5, Gesnera cardinalis; 6, Paulownia imperialis; 7, Thunbergia erecta; 8, Palisota Baxteri; 9, Panax fruticosum var. Guilfoylei; 10, Oreganum Majorana; 11, Alocasia Lowii.

Walnuts Failing.—*E. W. P.* Although some of the Walnuts appear to have been pecked by birds, others exhibit symptoms of attack by a bacterium. We are unable to diagnose the trouble until an examination has been made of some of the shoots on which the fruits were borne.

Abstract Published.

318,909.—Manures. Johnson, J. Y., 47, Lincoln's Inn Fields, London.—(I. G. Farbenindustrie Akt.-Ges., Frankfort-on-Main, Germany).

The mixed fertiliser described in Specification 236,494 and consisting of urea, ammonium phosphate, and potassium nitrate, the latter of which may be partly or completely replaced by potassium sulphate, is modified by replacing the urea wholly or in part by sodium nitrate, the ingredients being used in such proportions that nitrogen, phosphorus (calculated as pentoxide) and potassium (calculated as oxide) are present in the product in substantially the proportions 1 to 0·6 to 1·5. The potassium nitrate or sulphate may be replaced wholly or in part by potassium chloride. Specifications 30,683/97 and 231,021 also are referred to.

The Behaviour of Plants.

It might seem on first thoughts far-fetched or fanciful to write of the behaviour of plants; but to anyone who studies them there is nothing fanciful or far-fetched in the expression. Plants behave, indeed, in varied and often inscrutable ways. Let the tip of a root touch a hard object, and lo ! the root tip moves away from that object, so that, like a slow worm, it continues to glide its way through the soil. Pinch off the growing point of a young seedling Bean or Pea, and the odds are that a dormant bud in the axil of each of the cotyledonary leaves begins to grow out, so that there are presently two shoots instead of one. Yet had the main shoot been left alone neither of the cotyledonary buds would have ever grown at all. Such facts as these—and they could be multiplied a hundredfold—give much occasion for thought. Yet until recently the thought which such facts had occasioned remained extremely barren and, like barren thought, generally found expression in copious words. Now, however, knowledge, which so long had lingered, begins her slow approach. The instance of the developing cotyledonary buds may serve to illustrate the direction from which knowledge is making her way. It is, of course, easy to suggest reasons why the buds in the axils of leaves should have their fate—their life or death—determined by the main shoot. The most usual "explanation" used to be that the main shoot absorbed so much of the available food materials that the little left to the cotyledonary buds sufficed merely to keep them alive and provided nothing for their growth. The fact that if only the terminal bud of the main shoot is removed, and the rest of that shoot with its leaves is left, the same result is obtained, could also be explained by the assumption that it is the terminal bud which gets all the food materials. But since assumptions are generally false, it is as well to cultivate a habit of respectful doubt towards them. Nevertheless, the doubt must be what Huxley used to call "active scepticism." The doubter must suggest an alternative. That is sometimes easy. In the present case, for instance, it is not difficult to imagine that the apical bud of the main axis exercises in its own interest a veto on the growth of the cotyledonary buds; like an eastern potentate who slays his rivals to keep himself king. If so, the veto might be exercised in one of two ways. Either, in spite of all appearance to the contrary, the plant has a sort of nervous system and is able to send messages along nerves from one part to another; or else the messages which the plant transmits from one of its members to another are not of the nature of nervous impulses, but chemical in kind. Quite recently,* Mr. R. Snow, of Magdalen College, Oxford, has shown that the latter alternative is probably the correct one. He treated young seedlings of Broad Bean Johnson's Long Pod in the following fashion. The main stem (epicotyl) of the young seedling was cut off. The cotyledonary buds grew out and formed each a lateral shoot. From such seedlings with lateral shoots of nearly equal length one of these shoots was cut off above its second leaf and one bud was removed from the axil of one of these leaves, so that the shoot, with its head, had only one bud and that a lateral. This bud failed to grow week after week. The apex of the intact lateral shoot would not let it. So the question arose, how does it stop the lateral from growing ? If the stopping or inhibition is of nervous origin, cutting through the lateral just below the bud will effectively stop the passage of any nervous impulse; so also will killing a length of stem below the cut, and the latter method has the advantage over the former that it still leaves the wood vessels connecting the lower with the upper part of the injured stem. Accordingly, Mr. Snow killed by means of a hot glass rod about one-sixth-of-an-inch of the stem just below the axillary bud. In one half of the experiments the terminal bud of the other lateral shoot was left intact, and in the other half it was removed. The result was startling. The lateral bud just above the dead stretch of stem grew twice as fast when the apical bud of the other shoot was removed than it did when that bud was left intact. Therefore, it follows that the intact apical bud sends down a chemical substance which, passing through living tissue, reaches presently the burnt dead zone. There it is not stopped. The hormone exudes into the wood vessels, passes up with the transpiration stream into the living tract above, reaches the bud and holds up its development. Remove the apical bud and the restraining chemical message is no longer despatched, and so the lateral bud is free to grow. It is probable that all those wonderful facts of balanced growth and development which plants accomplish casually every day of their lives are brought about by means similar to those whereby the apical bud says to the lateral—thus far and no farther !

Our Supplement Plate.—The illustration presented as a Supplement Plate with the current issue represents a large border of Stocks which was a feature at Foxdenton Park, Chadderton, Lancashire, during the past season. This display attracted many thousands of visitors. Foxdenton Park is only six acres in extent and is under the control of Mr. Holland, Parks Superintendent to the Foxdenton Urban District Council, and is a wonderful example of cultural skill and patience as it is situated in the midst of hundreds of tall mill chimneys. Six years ago it was merely an untidy bit of land, now it is a lovely garden. Mr. Holland makes a special feature of Stocks, many kinds of hardy and half-hardy annuals and Dahlias. The park contains bowling greens and a natural dingle and ornamental water.

The "Gardeners' Chronicle" Almanac for 1930.—The preparation of our Almanac for 1930 is now proceeding, and as we are anxious to include so many dates of horticultural exhibitions and meetings as possible, the secretaries of horticultural, botanical and kindred societies are invited to send us the dates of their fixtures for the coming year, to reach us on or before December 31, 1929.

A Hybrid Poppy.—At the late November meeting of the Linnean Society, Mr. W. C. Worsdell exhibited a dried specimen of a hybrid Poppy. He stated that the plant was discovered in a garden at Ashford, Kent, in July, 1929, and cannot be matched with any known species. That it is doubtless a hybrid is supported by the fact that, although capsules are formed, no seeds are produced. The present view is that it is a cross between Papaver somniferum and P. Rhoeas, both of which were abundant in the garden. The plant is intermediate in several ways between those two species, *e.g.*, it is sparingly hairy, whereas P. somniferum is glabrous and P. Rhoeas is very hairy. The foliage is glaucous, but is more deeply cut than is usual with P. somniferum. The peduncle bears appressed hairs, as in some varieties of P. Rhoeas. The flower is scarlet, as in P. Rhoeas. The influence of the last species is also shown by the overlapping lobes of the stigma, whereas those of P. somniferum do not overlap. The appearance of the plant when growing was that of an Opium Poppy bearing scarlet flowers; this colour is unknown in this species. No published description of such a hybrid has been seen, but only the bare statement in Fedde's Monograph in Engler's *Pflanzenreich* that such have been artificially produced.

Preservation of Fruits and Vegetables.—In seasons when fruits and vegetables are plentiful, it is often desirable and economic to preserve some for use at other times of the year, and with a view to instructing fruit and vegetable growers in general as to the best methods whereby this end can be attained, the Ministry of Agriculture has issued a valuable booklet entitled "Domestic Preservation of Fruit and Vegetables," (Miscellaneous Publications, No. 69, price 1s. in paper cover, 1s. 6d. quarter-bound) which may be obtained at the Ministry's offices, 10, Whitehall Place, London, S.W.1, and should prove of value to all who grow fruits and vegetables, or are able to obtain them cheaply. The publication has been compiled, at the request of the Ministry, by the workers at the University of Bristol Research Station, the various methods and recipes given of those found most suitable only after repeated experiments; only simple methods of preservation, which do not entail the use of chemicals or dyes and can be carried out in the ordinary household, are given. The principles of fruit and vegetable preservation are dealt with briefly in the opening chapter. The various causes of spoilage—yeasts, moulds and bacteria—are discussed, also the chemical effects of preservation, the process of dehydration (removal of water), and the chemical preservative actions of sugar, salt and vinegar. Chapter II deals with fruit canning, the selection and preparation of the different fruits being discussed very lucidly, and the methods of canning described in detail. The various essentials of successful fruit bottling, with the best methods of procedure, are explained in Chapter III, and the succeeding chapters are devoted to jam-making from fresh fruits; fruit jellies; fruit syrups; candied, crystallised and glacé fruits; the preservation of vegetables by canning and bottling: the drying of fruits and vegetables as a means of preservation: and the making of chutneys and pickles, so it will be seen that the whole subject of fruit and vegetable preservation is dealt with in a comprehensive and concise manner. Numerous recipes are given for each subject, and the booklet is well illustrated with excellent diagrams and photographic reproductions.

---

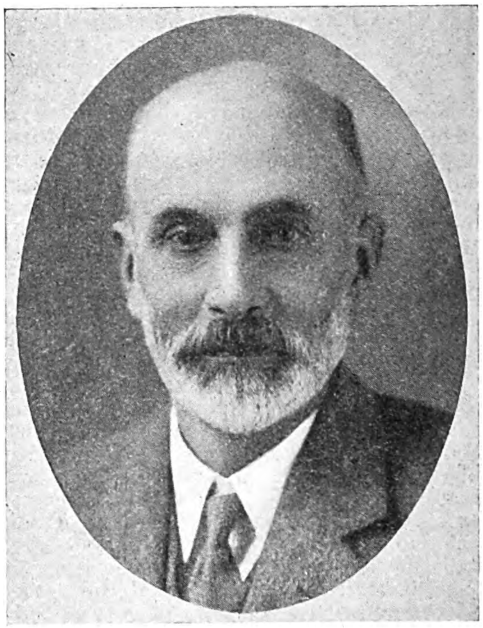
* "The Transmission of Inhibition through Dead Stretches of Stem, by R. Snow. *Ann. of Bot.*, XLIII, No. CLXX, April 1929.

Christmas Shopping.—Most kinds of shopkeepers understand the psychology of Christmas shopping, but horticultural traders—florists excepted—do not appreciate the fact that a seed shop pleasingly decorated, especially if the weather is fine, may prove a great attraction to the general public and create business. Messrs. James Carter and Co, of Raynes Park, fully appreciate this natural tendency prior to Christmas time, consequently they provide unusually attractive horticultural displays in the windows of their London shops in Regent Street and Cheapside. At Regent Street the arrangement of Heaths and Ferns, bulbs and bowls, horticultural pottery of many beautiful kinds, gnomes, Fir-cones made to resemble quaint birds, Lavender sachets, pigmy trees, and miniature Japanese gardens, creates an attraction that is irresistible; to stop and look is to enter, to enter is to buy. In the basement are additional attractions in the form of sundials, more gnomes, garden ornaments of many kinds, and flower bowls in great variety and beauty, among which the clouded amber glassware, the Minton ware and the Dutch designs are so intriguing that the desire to possess some of these works of art overcomes all other considerations.

International Rose Competition at Barcelona.—We learn from the continental horticultural press that no fewer than ninety-two varieties of Roses were sent in for the first international Rose competition to be held at Barcelona, Spain. The authorities of the Bagatelle competition, which has been established now for many years, will have to look to their laurels, as only thirty-six new varieties figured in the Bagatelle Rose trial lists this year.

Jubilee of a Dutch Nursery.—It is just fifty years since the foundation in Boskoop, Holland, by H. den Ouden—father of the present proprietor—of the well-known Old Farm Nurseries. Strawberries were originally the principal product, with fruit trees, ornamental shrubs and Conifers as additional items of cultivation. In 1896, Mr. P. den Ouden, the son of the founder, became associated with his father in the business, and the scope was enlarged to include Rhododendrons, Azaleas, Clematises and other subjects; glasshouses were erected, and the firm began to export abroad. In 1898, the founder retired, but the business continued to expand, especially in its export trade, which soon became very active with Great Britain, North America, Germany and Belgium. The American regulation known as "Quarantine 37," which was passed about 1917, had the effect of almost destroying the carefully built-up trade with the United States, but, in compensation, export to Canada and to British Columbia increased considerably. A speciality is now made of dwarf and other Conifers, of which great numbers, planted before the war, are coming to perfection. Rhododendrons and Azaleas are still cultivated on a considerable scale, and the firm also specialises in Phloxes, Irises and in Chinese, Japanese and single-flowered Paeonies, of which 60,000 are grown every year. Another subject grown is Gypsophila paniculata var. Bristol Fairy, of which a large field in full bloom makes a very beautiful sight. Mr. den Ouden is very particular about nomenclature in his catalogues, and is a member of the Nomenclature Committee of the Netherlands Dendrological Association. To celebrate the Jubilee of his firm, he has brought out a fine catalogue in English. Mr. H. den Ouden, son of the present proprietor, is a frequent visitor to this country, and is well-known to commercial horticulturists; he is an accomplished linguist and has travelled extensively in European countries.

Mr. H. H. Mills.—For the past eighteen years, Mr. H. H. Mills has held the post of gardener to Hugh Morrison, Esq., M.P., and Lady Mary Morrison, at Fonthill House, Tisbury, and during that period the flower garden and pleasure grounds have been re-modelled, this work being rendered necessary by the building of a new manor house. A feature of these gardens is the extensive use of climbing plants, and such subjects as lend themselves to training against walls and fences; purely ornamental plants are usually alternated with fruit trees, and this unusual arrangement adds to the utility of the garden without detracting from its beauty. Mr. Mills is a native of Northamptonshire, and as his father had served at Castle Ashby, Margam Park and Calderstones, it was not surprising that the son became a gardener. He commenced his gardening career at Mintern House, Dorchester, under his father, and afterwards applied himself to landscape gardening for a period before becoming foreman, in succession, at Milton Abbey and Sherborne Castle. His first position as head gardener was at Pyt House, Tisbury, Wiltshire, and he subsequently held similar positions at Rushmore, Gweenyfed Park and Holmwood Park, before taking up his duties at Fonthill House. Mr. Hills is a first-class gardener, and is especially expert in the cultivation of hardy fruits. Apart from his duties at Fonthill House, Mr. Mills interests himself in village life, is Secretary of the Tisbury and District Beekeepers' Association (he is an ardent bee-keeper), and a member of the Committee of the Wiltshire Horticultural Growers' Association.



MR. H. H. MILLS.

The Largest Davidia.—The following communication from Mr. G. Brooker, Buckhold Gardens, Pangbourne, will be of interest to many readers who cultivate Davidias:—"In your issue of May 18, 1929 (p. 366), M. Correvon stated that there was a very large specimen of Davidia involucrata in M. A. Gérard's arboretum at La Fosse (Loir et Cher), planted in 1906, and thirty-eight feet tall. We have a tree, which was measured last week (December 2), with the following results:—Height, forty-two feet; approximate spread of branches, forty feet; trunk at ground-level, three feet three inches; trunk at three feet from the ground two feet five inches: first bough, one foot three inches from the ground. This tree was planted about 1902, and this season it carried between four hundred and five hundred blooms, but not more than eighteen nuts were found at the time of leaf-fall."

Legacies to Gardeners.—The late Theodore Pim, Esq., of Snowdenham Hall, Bramley, Guildford, bequeathed £800 and a life annuity of £70 to his gardener, Mr. A. J. Joy; £250 to each of six members of the garden staff; £100 to one member, and £50 each to two others.

Sale of Rhododendrons and Azaleas.—Large collections of Rhododendrons, Azaleas, Camellias, Japanese Maples and Magnolias, gathered from all parts of the world, may be seen at The Camp, Windlesham, near Sunningdale, and Messrs. Knight, Frank and Rutley have been instructed to sell them privately in large or small quantities. Amounting to many thousands in number, and in hundreds of rare and varied species, they include 4,000 Chinese, Himalayan and hybrid Rhododendrons, 4,000 Azaleas, 1,000 Kalmias, 200 Camellias, with some hundreds of Andromedas, Hydrangeas, Prunus Pissartii, Maples, Magnolias, Scarlet Oaks, Cotoneasters, Viburnums, and many fine varieties of Pyrus.

Australian Fruit Trade Developments.—Following on the visit of Mr. Harold Ford, Secretary of the Clyde Trust, to Australia, and subsequent negotiations with the principal fruit importers in Glasgow, arrangements were concluded at a conference held at Liverpool whereby direct shipments of Apples will be made to Glasgow next season, instead of via London as formerly. Seven firms have promised to support the scheme and to cope with the fruit requirements of the Glasgow market. Messrs. Alfred Holt and Co. have agreed to put in the service five steamers of the Blue Funnel Line, provided with refrigerated space, to ensure a regular supply of fruits throughout the Australian season. The first steamer (S.S. Nestor) is due to arrive in the Clyde about April 25, and the others will follow at fortnightly intervals. Producers in Australia and Tasmania attach great importance to the scheme, as Glasgow is one of the largest fruit distributing markets in this country, serving as it does the whole of Scotland and the north of England.

The Need for Practical Forestry.—Colonel W. Stewart Fothringham, Murtly Castle, delivered his presidential address to the members of Edinburgh University Forestry Society on Thursday, November 21, when he chose for his subject, "Some Ramblings on Practical Forestry." In the course of his observations he impressed upon his audience that the very best instructors they could get were the trees themselves. It was true that trees were dumb, but they had a way of expressing their appreciation of the way in which they had been treated which was easily read by the trained eye. Observation and experience were the surest roads to success in practical forestry. In Great Britain they had always been ready enough to cut down timber and make the best use of it, but they had not hitherto bothered themselves to grow timber, which was absolutely necessary. There had always been a few men in this country who had devoted their time and attention to forestry, and found it a most absorbing study and one which never came to an end. They had been a small band who had never turned back and were thoroughly enthusiastic. They would have followers, and he hoped the followers would be a great deal more numerous than the leaders themselves. At the dinner which followed, Professor E. P. Stebbing, in proposing the toast of "Forestry," said he had received a letter from the Colonial Office pointing out the deficiency in numbers of qualified men who had presented themselves for selection for appointment last July, and asking how many there would be next year. He was not able to hold out high hopes for 1930 or 1931, but was able to say that they had a much stronger body of first year students. At the present moment the yearly growing and expanding Empire Forestry Services were unable to obtain the men they required, and certain services were actually being delayed in necessary expansion because the number of qualified men was short of the demand. That being so, he appealed to the press to give their assistance in ventilating this matter in order that all classes in the country might be made acquainted with the present situation.

Gift to the Royal Gardeners' Orphan Fund.—At a recent Court Meeting of the Worshipful Company of Gardeners, under the Master, Mr. Edward Sherwood, it was decided to give the Royal Gardeners' Orphan Fund an additional holding of three-and-a-half per cent. Conversion Loan Stock, so as to increase the allowance of the orphan provided for by the Company from the original 5/- to the 7/6 per week which the Fund now makes to the children under its care.

The Harvard Botanic Garden.—We learn, through an American contemporary, that by a recent order of Dr. A. Lawrence Lowell, the President of the Harvard University, the Harvard Botanic Garden, probably the oldest institution of its kind in America, has ceased the horticultural activities which it has carried out for a number of years, and will in future be used exclusively by the department of botany for scientific purposes, with Dr. R. H. Woodworth in charge. The Harvard Botanic Garden was founded in 1807.

Big Sale of Scottish Standing Timber.—Messrs. A. and G. Paterson, of Glasgow, Aberdeen, etc., have just concluded with Lord Forres the purchase of some five hundred acres of standing timber on his Lordship's Glenogil estate in Forfarshire. The deal was carried through by the Landowners' Co-operative Forestry Society, Ltd., Edinburgh, who acted for Lord Forres. The trees consist principally of finely-grown mature Larch, the quality of which is excellent, as is invariably the case in the northern part of Scotland. Included also are Scots Fir and a remarkably fine stand of Norway Spruce grown at an altitude of 850 feet. The latter are now sixty-four years old, and when measured in 1920 gave a mean height of seventy-two feet and a mean quarter-girth of nine-and-a-quarter inches. It was computed there were then about five hundred stems to the acre, with an overbark volume of 10,000 cubic feet. Messrs. A. and G. Paterson have for over a hundred years taken a most prominent part in the home timber trade of Scotland, and there are very few wooded estates on which they have not conducted felling operations, and with their travelling saw-mills have turned to commercial uses vast tracts of Scottish woodlands. It is understood the transaction will mean work for a large number of men for the next seven years.

National Sweet Pea Society.—This special flower Society has again arranged two fixtures for the coming year. The Annual Show will be held in the new Horticultural Hall, Westminster, on July 8 and 9, while the Provincial Show is to be held at Southsea, in conjunction with the Annual Show of the Portsmouth Horticultural Society, on July 23, 24 and 25, 1930.

British Wood Preserving Association.—A British Wood Preserving Association, whose object will be to spread knowledge of methods of wood preservation with a view to preventing wastage of timber supplies, was formed at a meeting held at the Hotel Metropole, London, on December 3. Among those attending the meeting were representatives of several Government Departments, the several Schools of Forestry and Forestry Societies, the Central Landowners' Association, the Timber Trade Federation of the United Kingdom, many firms engaged in wood preservation or the manufacture of wood preservatives, and a number of estate owners. Unfortunately, a meeting of the Council of the Royal Horticultural Society fixed for the same afternoon, prevented that Society being represented. The Association was formed on the proposition of Lord Clinton, late Chairman of the Forestry Commission, and among others who spoke in support of the formation of the Association, in addition to Sir Harold Boulton and Sir James Calder, at whose invitation the meeting was called, were Colonel Sir George Courthorpe, M.P., a member of the Forestry Commission; Sir Peter Clutterbuck, Chairman of the Empire Forestry Commission and late Inspector-General of Forests to the Government of India; Mr. C. J. Brown, of the L.N.E.R. Engineers' Department; Mr. C. Le Maistre, British Engineering Standards Association; and Mr. Bryan, of the Forest Products Research Laboratory. Sir George Courthope said that the Forestry Commission would welcome the formation of the Association, and he hoped that it would be possible for the Association to provide readier access to preserving plants for home-grown timber, which at present is severely handicapped in that respect in comparison with imported timber. Sir Peter Clutterbuck, referring to the shortage of soft-wood supplies, said:—"It is not generally realised that if we can make wood last longer by adopting preserving methods, we shall be doing as much good as would be done by increasing our supplies of timber. That alone is an enormous justification for the Association." Lord Clinton, referring to the possibility that by the use of preservatives certain timbers which are now unpopular might be made available for commercial use, said: "You can confer no greater boon upon the producer, the forester, of this country than by doing something of that kind." A temporary Committee, representing a number of interests, is being formed to draw up the constitution, etc., of the Association, and will report in due course to a General Meeting. The temporary offices of the British Wood Preserving Association are at 166, Piccadilly, W. 1.

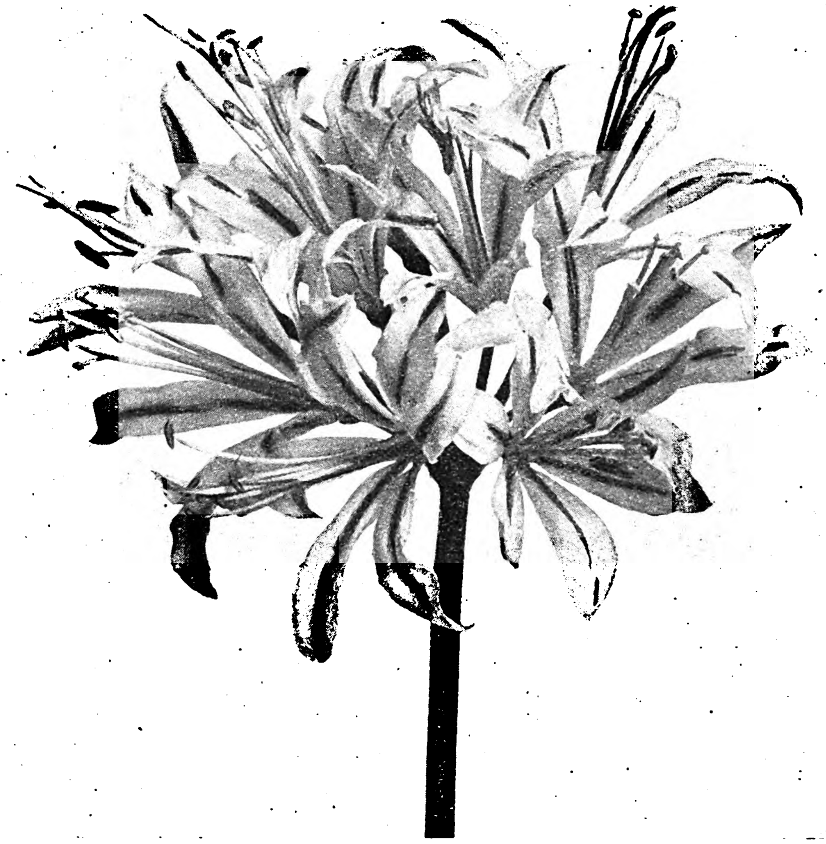


FIG. 209.—NERINE ATTAR.

(see p. 465.)

Honour for Professor Augustine Henry.—We are glad to learn that the Academy of Agriculture of France has honoured Professor Augustine Henry, of University College, Dublin, by electing him a Corresponding Member in recognition of his services to forestry. We may remind our readers that in addition to his work on forestry and his association with the late Mr. Elwes in the production of *The Trees of Great Britain and Ireland*, Professor Henry was a most successful collector of plants in China, whence, some thirty years ago, he discovered about a thousand species new to science, many of which are now in general cultivation.

Appointments for the Ensuing Week.—MONDAY, DECEMBER 16: Harrogate and District Horticultural Association's meeting; National Chrysanthemum Society's Floral Committee's meeting. TUESDAY, DECEMBER 17: Winchester Horticultural Society's meeting. THURSDAY, DECEMBER 19: Newcastle and District Horticultural Society's meeting; Ipswich Gardeners' Association's meeting. SATURDAY, DECEMBER 21: Leeds Paxton Society's Flower Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Botanical Names for Novelties.*—We have had the misfortune, it seems, to hurt the susceptibility of a respectable German botanist. In our number for April 22, of the present year, we presumed to criticise the "bad German habit of attaching to every supposed novelty a long Latin description, four-fifths of which are superfluous." At this Dr. Steetz, whose contributions to the Botany of the *Herald* called forth the remark, has taken offence. We really had no intention to say anything disagreeable to the learned gentleman; but it was our duty to animadvert upon a pernicious though well-meant practice, which has already rendered systematical botany more chaotic, and infinitely more uninviting than it was when Linnaeus swept away its rubbish; and upon re-perusing the remarks in question, we are at a loss to know in what manner our opinion could have been expressed with greater courtesy, so that our meaning should be unmistakable. Surely Dr, Steetz cannot think himself above criticism; and most certainly we have not regarded him as being beneath it.—*Gard. Chron., December* 16, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

The Cool Orchid House.—Where a quantity of cool house Odontoglossums is grown, graceful spikes of flowers may be had practically the whole year round. Besides the typical forms, many highly-coloured kinds, also the chaste O. xanthotes in variety, together with the brilliantly-coloured and free flowering Odontiodas and closely allied hybrids, are attractive features in collections, especially at this season, both as decorative specimens and as cut flowers; the long, arching spikes lend themselves admirably for such purposes. Numerous flower spikes are now being produced, and where slugs are troublesome, the flowering specimens may be placed on inverted flower pots stood in saucers of water, or cotton-wool may be placed around the bases of the spikes and frequently renewed to maintain a loose surface which prevents the slugs from passing over it. Lettuce leaves, saucers of bran and cut Potatos, may be used as traps, and should be examined for the pests at night. The bases of the spikes should be secured to neat stakes at an early stage, before the lower portions become hard and difficult to keep straight. Ample ventilation should be given during favourable weather, care being taken to avoid cold draughts so much as possible by using the ventilators on the leeward side while strong or cold winds are prevailing. The plants are in various stages of growth, and the object should be to keep them growing steadily and sturdily. Care is needed when affording water to the roots. The very late-potted plants only require small quantities of water poured around the pot rim, while others that are well-rooted, and especially those developing pseudo-bulbs and flower spikes together, need larger supplies of water at the roots each time the compost approaches dryness. After flowering, less water will be required for a few weeks, although long periods of drought should not be allowed. The amount of damping down to be done will depend a great deal on the weather and the aspect and altitude of the houses. In low-lying districts, during mild weather when very little fire heat is used, very little damping is required at this season, sufficient moisture being afforded by the necessary watering of the plants. When fire heat is employed to maintain the necessary temperature more moisture is naturally required to counteract the dryness in the atmosphere. At this season, in most districts, damping once a day is sufficient, but in high and dry districts it will probably be necessary twice a day, especially during windy weather. In smoky districts the outside of the glass will require washing occasionally, especially after thick fogs, in order to secure so much light as possible for the plants. Small thrips are often troublesome on these Orchids and should be keenly sought for and destroyed, as they quickly do considerable damage to the growths and flowers if allowed to remain. A little insecticide should always be kept at hand to cleanse infested growths with the aid of a feather or very small brush. Occasional fumigation on quiet evenings should help to keep the pests in check, but spraying with a solution of an approved insecticide at fortnightly intervals is more effective. This operation should only be done in the forenoon of a dry and clear day.

Pleiones.—As the early-flowered Pleiones, such as P. praecox, P. maculata and P. lagenaria, pass out of flower, repotting may be attended to, removing the soil and most of the roots but leaving a small tuft to secure the pseudo-bulbs in the new compost. Shallow, well-drained pans are suitable receptacles, and a compost of equal parts of A.1. fibre, cut finely, and good fibrous loam, with a little chopped Sphagnum-moss, and sharp sand or crushed crocks to keep it porous, should be employed. Allow sufficient room between the pseudo-bulbs for development, and when potted, place them near the glass in an intermediate house; very little water will be required for several weeks until growths and roots are active.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Fruit Tree Pests.—Fruit trees that were grease-banded early in October, to catch the wingless females of the mottled umber and the winter moths as they ascend the tree trunks, should be examined to see that the bands are in working order. For there is still a month or so in which some of these insects will be on the upward trek. This ascent may occur at any time from the first week in October until the middle of January. The majority, however, are caught on the bands between November 25 and the end of the first week in December. From observations carried out on "banded" Apple trees in an orchard in north Berkshire this season, some one-hundred-and-ten female winter moths were caught on a single band before November 21. During the following eight days, however, four-hundred-and-forty additional female moths ascended and were caught on this same band, which goes to show how very important and effective a measure is this system of grease-banding fruit trees. Some of these insects were examined with the view to ascertaining how many eggs each female was capable of laying, and the average worked out at over two hundred each. Of the caterpillars which attack the leaves of our fruit trees, that of the winter moth is, without doubt, the most serious pest. The females are practically wingless and are obliged to ascend the trunks of the trees to lay their eggs on the twigs and branches. This fact, and the introduction of the "sticky-band," has provided gardeners with a ready means of prevention. It must not be overlooked, however, that grease-banding is useful only against wingless moths and, when applied at this season of the year, will only prevent the two moths mentioned above from depositing their eggs on the branches. To prevent the wingless female March moth from ascending to the branches, the bands should be renewed, or kept in a sticky condition from February until April, as it is during that period that this destructive pest ascends to lay her eggs. There are several very destructive moths, such as the lackey moth, the vapourer, the lappet and the small ermine moth, the females of which either possess wings or, as is the case with one, she rarely leaves the tree. As a preventive measure, grease-banding against these would be futile, but much may be done by observant pruners to reduce the number of these pests at this season.

The Lackey Moth (Clissiocampa neustria).—The eggs of the lackey moth are arranged in single-layer bands, half-an-inch to one inch in depth, around the twigs of the trees. They are placed there in July or August, and remain until the caterpillars are hatched out in the following April. The caterpillars are dark at first, but later become brilliantly striped from head to tail, and have two conspicuous dark spots on a rather large head. The egg bands, when seen, should be cut away, or, if this means the destruction of some important shoot, paint the egg bands with methylated spirit.

The Vapourer Moth (Orygia antiqua).—The eggs of this moth are quite conspicuous as they are generally arranged in a single-layered mass on the old cocoon case in a fork in the branches. This egg cluster may be as large as a penny, irregular in shape, and containing upwards of two hundred eggs. Their removal presents no difficulty. The eggs hatch out towards the end of April, and the furry caterpillars are easily recognised by their having four tufts of creamy-white hairs down the centre of the back.

The Small Ermine Moth. (Hyponomeuta padella).—This pretty moth deposits her eggs in scale-like masses on the twigs of fruit trees during August. Minute caterpillars are hatched out in September, and they spend the winter on the tree. The next spring they become active and enter the developing leaf-buds and flower trusses, causing considerable harm. Later, however, they associate in colonies protected by a silken web which is difficult of penetration by spraying.

The Lappet Moth (Lasiocampa quercifolia).—The caterpillar of this moth is not common, and possibly its great size and length, three to four inches, when stretched along the twigs, make it an easy prey to birds. It is the largest leaf-eating caterpillar we have in our orchards; but although this is so, it often escapes detection in the winter as it can assume the colour of the twig on which it is lying. The four pests mentioned and, of course, the eggs of all the aphidae, can only be controlled by a strong winter wash, such as any of the various forms of tar distillate, during the dormant season, or in spring by spraying the trees with arsenate of lead or nicotine.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Hippeastrums.—These, which are commonly referred to as Amaryllis, may be had in flower over a period of several months by judicious arrangement and forethought. A few of the best specimens should be selected to start into growth now; these should be given a thorough soaking with clear water and then top-dressed with a rich, light compost, after a portion of the old surface compost has been carefully removed. Examine the bulbs for insect pests. Mealy bug is very partial to these plants and, if present, the bulbs should be cleansed with an insecticide after all the loose scales have been removed. Arrange the plants on a mild hotbed, and for the time being very little water will be needed; if overwatered, leaf growth will be made instead of flower-spikes. A moist atmosphere, however, is essential, and if it becomes at all dry the pot should be syringed with tepid water. Seedling Hippeastrums raised this year should be kept growing through the winter in a temperature ranging from 55° to 60°.

Humea elegans.—Young plants of Humea elegans raised from seeds as advised, should be potted on into larger receptacles as they become ready, using a light, open compost for this purpose. The plants should be grown near the roof glass under the coolest possible conditions, and fresh air should be allowed to circulate freely around them whenever the outside conditions are congenial. Humeas should be kept in an even state of moisture at the roots as they are impatient of either extreme dryness or excessive moisture.

Coleus thyrsoideus.—This is one of the most useful of winter-flowering glasshouse plants, especially when timed to produce its bright blue flowers in January, when flowers are none too plentiful. The plants are now developing their flower spikes, and to improve the length of stem and also the brightness of the flowers they should be fed occasionally with liquid manure and soot-water. A temperature of 55° should be found suitable for them, and they should be placed in a light position near the roof glass to prevent the plants becoming drawn.

Allamandas.—These stove or intermediate house plants may now be pruned, cutting the long shoots back as desired. Where no extension of growth is required, cut the growths back to about four buds. At this season the plants should be kept comparatively dry at the roots.

Azalea indica.—To augment the supply of decorative plants early in the New Year, a few plants of Azalea indica that are well set with flower buds may be placed in gentle warmth, although no attempt should be made to force them rapidly.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Figs.—Pot trees which were moved under glass as advised last month may now be plunged in a steady bottom-heat and syringed judiciously with tepid water, when their terminal buds should soon show signs of activity. This will justify the maintenance of a rather moister atmosphere and a slightly higher temperature on bright days, but no advance should be made yet on the night temperature. As the trees progress the mean temperature may range from 50° to 55° at night, and about 65° by day, a little higher or lower according to the state of the weather. It is better to err on the safe side than to hurry the trees into growth through the remainder of this month. Established trained trees may now be started with every chance of success. If there is room for a little fermenting material this may be placed loosely around the cubes of compost, and the warmth and moisture from this should soon start the trees into growth. Care should be taken that before applying the fermenting material the compost should be restored to a moist condition by repeated applications of water at a temperature of 85° to 90°. By adopting this mode of starting the roots and shoots simultaneously, and keeping the floors and walls regularly damped, direct syringing, except in the middle of fine days, will hardly be necessary.

Midseason and Late Figs.—If these have not already been pruned, this operation may be done at any time now, and the trees washed on wet days, but not when frost is likely to occur. Top-dressing of the soil and lime washing the walls should follow, and, when all is completed, the houses should be kept dry and airy until after the turn of winter.

Propagation of Figs.—If young Fig plants are wanted, select a few of the ripened shoots and place them in a cool and safe place until the time arrives for rooting them. They root freely with the aid of bottom heat, or failing this, plants may be raised from short, sturdy growths inserted singly in small pots, after being divested of their lower buds.

The Grape Room.—The old method of allowing late Grapes to hang on the vines until March has gradually been superseded by the practice of cutting and bottling the bunches early, for by this method the berries may be kept in a plump and satisfactory state for four or five months. Late vines now have a good three months' rest before them and require a minimum amount of fire-heat. Light is not an absolute necessity for the Grapes in store, but should be admitted if the berries damp, which, however, does not often occur if the room is dry and a temperature of about 45° maintained, with ventilation to dispel any moisture. Loss of water in the jars, especially for the first few days, should be made good, and any faulty berries removed.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Sweet Peas.—The ground for next season's Sweet Peas should be prepared so soon as possible. Various methods of soil preparation are adopted. Some trench the entire area, while others simply prepare the actual sites where the clumps are to be planted. Open and prepare wide trenches if it is proposed to grow them in lines. Whichever method is practised, deep and thorough cultivation is essential. The ground may be trenched or bastard trenched, according to the condition it is in. If it has been under cultivation for a long period, the second and even the third spit ought to be quite good, and trenching should be adopted; if, on the other hand, it is of a wet, cold, clayey nature, bastard trenching will be best. Incorporate plenty of well-decayed manure as the work proceeds, putting the first layer well down so that the plants may derive full benefit from it when they become established. If the method of taking out holes or trenches is adopted, it is advisable to open them so soon as possible, giving a good dressing of manure in the trench after the bottom has been deeply broken up with a fork. Allow the trench or hole to lie open during the winter months so that the soil which is to form the growing medium may receive the full benefit of the action of wintry weather. This latter method has a distinct advantage in that decayed loam or other suitable compost may be spread along the sides of the trench and can be readily mixed with the staple soil as the trench is being filled in early spring in preparation for sowing or planting.

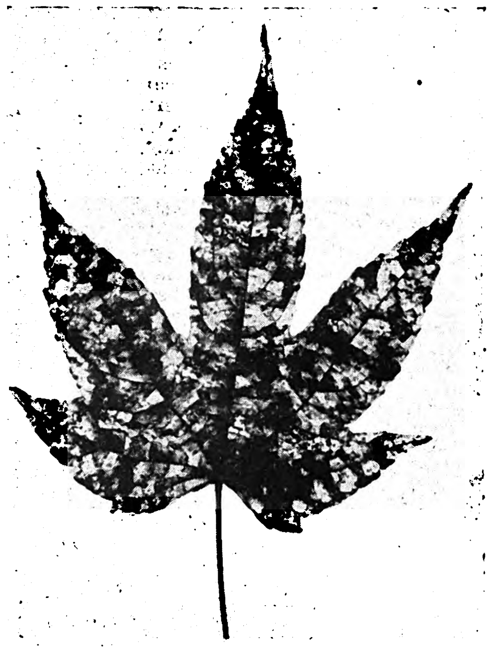

FIG. 210.—ABUTILON THOMPSONII.

(see p. 468.)

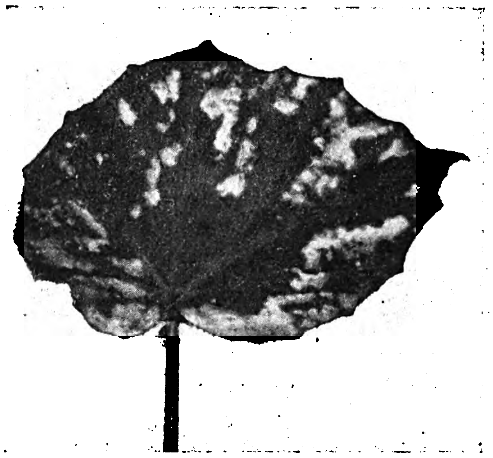

FIG. 211.—BEGONIA MANICATA VAR. VARIEGATA.

(see p. 468.)

Flower Beds.—Any beds that are to be vacant during the winter should be dug at the earliest opportunity and the soil left rough, so that frosts may prove beneficial to it; this applies particularly to soil of a heavy texture. Manure the beds, if necessary, according to what they are to be planted with during the coming season.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Asparagus.—Where the growths of Asparagus have still to be cut down, this should be done at once, the beds edged, and then mulched with well-decayed manure. Only a moderate coating should be given as if laid on the beds too thickly the soil will lay cold and damp through the winter. Young Asparagus plantations should also be cleaned and lightly mulched.

Herbs.—Roots of such herbs as Mint and Tarragon which are required for forcing should now be lifted, packed in boxes, and after being thoroughly watered, placed in moderate heat.

Vegetables in Store.—Where root crops have been in store for some time, they should be inspected, and any growths on such subjects as Beetroot and Carrots rubbed off. Potatos, although apparently quite sound when placed in the store room, should also be sorted and any decayed ones removed, or others may become affected. A few "seed" tubers for early forcing may be brought into the light. Ten-inch pots are suitable for forcing them in, and should be half-filled with a compost of good loam and a little leaf-mould. Having set the tubers, the pots should be placed in a house with a temperature of 50° to 55°; if the temperature is higher, the haulm will become thin and drawn and a poor crop will result. Heated frames may also be employed for forcing Potatos, but plenty of covering material will be required as protection from frost.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq. Rosemount, Monkton, Ayrshire.

Ground Operations.—Although the ground in many cases may be much too wet for working, much useful work can be carried out in improving lawns, pleasure grounds, grass edgings, etc. On the lawns there may be hollows to fill up or mounds to remove, and this work should be attended to. If large areas have to be dealt with, the grass should be carefully cut and stacked while the filling in or removing is proceeding. Ashes prove a very suitable material for raising low areas on lawns, and should be used in preference to soil, and when employed work can be proceeded with even during wet weather. When raising small areas on lawns it is only necessary to cut the grass with an edging iron and roll it back, replacing it after filling the depression with suitable material, and making it quite firm. Grass edgings often become sunk in places, and these may be put right by raising the turf with a spade, packing ashes or soil beneath and beating it level.

Planting Shrubs.—Any planting or rearranging of shrubs may be done when the soil and weather conditions are suitable. Deciduous shrubs of all kinds may be moved with impunity while at rest, and many of the commoner evergreens as well, but with the finer or rarer evergreens it is not advisable to move them until growth is started in April or May; this applies also to such hedging evergreens as Hollies and Yews.

The Rock Garden.—Hardy as most rock plants are, many of them suffer severely during our erratic winters. They seem to languish for the comfortable blanket of snow to which they have been accustomed, and perish in our alternating rains and frosts. Those of a downy or hairy nature at least should have a sheet of glass or slate placed over them to ward off dampness, and if well mulched with lime, granite or even whinstone chips, should benefit greatly. It is a mistake to lift rock plants and winter them in frames, as is sometimes done, as the root systems of most alpines do not lend themselves to transplanting, so that, even if the plant survives, the check it receives renders it incapable of flowering in a satisfactory manner. Where large patches of Androsaces, Onosmas, Raoulias, etc., are grown, a sheet of celluloid fitted into a light frame of wood makes a capital protection from rain, for if kept dry, these plants should survive the winter well.

TREES AND SHRUBS.

VIBURNUM RHYTIDOPHYLLUM.

THIS striking Chinese shrub was introduced by Wilson in 1900. It is well worthy of a place in all gardens where hardy shrubs are appreciated and should prove a handsome feature all through the year.

The ovate-oblong, deeply channelled leaves are dark, glossy green above, and covered with a dun-coloured, woolly tomentum beneath; they may be up to seven-and-a-half inches in length, and from one inch to two-and-a-half inches in breadth; as they are evergreen in character they retain their effectiveness throughout the year.

The flowers are of a yellowish-white hue, and are carried well above the foliage in terminal corymbs, each four to eight inches across. The buds are formed in the autumn, and they remain throughout the winter in a partly developed state, and expand during May and June. The flowers are followed by oval fruits which, during the autumn, are of a rich shining red colour, and during the month of September are particularly attractive.

Viburnum rhytidophyllum, in addition to making a good bush in the open, is an excellent subject for growing as a specimen plant against a warm wall. *T. H. E.*

VITIS STRIATA AND V. VINIFERA VAR. PURPUREA.

FOR gardens of limited area, or places too small to accommodate the greater Vines, Vitis striata and V. vinifera var. purpurea can be recommended. The former, also known as Ampelopsis sempervirens, is very similar in many respects to V. inconstans var. Veitchii, but I have not found it nearly so vigorous as that excellent climber, and it differs from the latter in being evergreen. I bought V. striata for covering an ugly wall no more than about eight feet in height. This it did with commendable speed and more, but, not being hardy, it is cut back by frost to about half its height every winter. The exceptionally severe frost of last March killed it to the ground, but it was soon up again and managed to cover its allotted space before the end of summer.

V. striata is a native of Chile and Brazil. It makes a number of slender, ramifying growths which are amply furnished with leaves averaging rather more than three inches across. These are composed of five almost stalkless leaflets which are neatly tapered and toothed and of a dark glossy green. The effect is that of a climber luxuriantly foliaged with rather small, daintily-cut leaves which, the winter being kind, retain their fine-toned green the season round. This is obviously a Vine for a warm wall. Even if it should escape beyond its given space, it is easily kept within bounds, and the fact that it is evergreen in a genus so largely composed of deciduous species is alone sufficient to bring it into notice. The young growths, I should add, are a bright red, and although the plant is "self-clinging" it needs something for its tendrils to grasp.

V. vinifera var. purpurea, the Teinturier Grape, is a delightful replica of the common Grape vine reduced to less than half its size and richly coloured. That this variety may be more robust in some soils I have no doubt, but a specimen I have has not exceeded ten feet in height in as many years. From spring to autumn the beautifully lobed and cut leaves which adorn its wine-red branches are a delicate green, generously suffused with claret-purple. This colour deepens towards autumn when, for a month, or even two months, the entire foliage is stained with a crimson-purple of extraordinary intensity. Grown on a pergola, pole or arch so that the leaves may be seen against the light, their colour becomes a vivid blood-red of a shade so brilliant that they have few rivals in their own hue, and none whose colour prevails over so long a period. Here, at any rate, this very ornamental vine is one of the earliest shrubs to show autumn's tints, and it is one of the last to shed its leaves. It may be that a rather poor, stony soil tends to intensify the leaf colour in my plant as well as to retard its growth, but I have seen it giving admirable effects under other conditions. The little clusters of plum-red Grapes which this vine will bear after a fine summer lend an additional touch to its decorative value, especially when the shrub is used on an arch so that the fruits may be seen from below.

MYRTUS NUMMULARIA.

THIS admirable little shrub was among the last things I received from that home of many good and rare treasures, the old Comely Bank Nurseries, of Edinburgh. It was planted in the open with that doubt as to its prospects which commonly accompanies the planting of Myrtles. But, instead of shrinking from the life before it in a northern home, this New Zealander has never once looked back. The severest winters most of us can remember have failed to inflict the slightest injury upon it and my original plant, now established some four or five years, is one of the heartiest things in the garden.

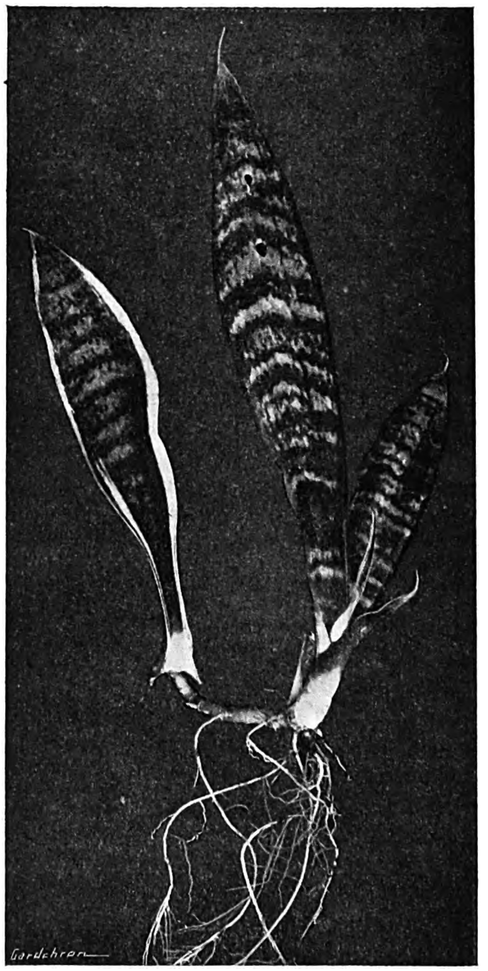

FIG. 212.—SANSEVIERIA LAURENTII.

(see p. 468.)

Myrtus nummularia is a perfectly prostrate, evergreen shrub. Its slender, rather brittle branches and their straight little twigs arranged with an irregular fish-bone angularity, are a bright mahogany-red, and along them are disposed the almost round, leathery, dark green leaves. The flowers appear in summer as fluffy balls of snow-white, perched along the upper sides of the creeping branchlets, and these are followed by globular berries which are white, flushed with pink. Both flowers and fruits have an obviously effective setting in the dark and sullen foliage.

It appears to enjoy a cool, free soil containing plenty of humus. Here it has only a small share of the sun, and to that it seems to be indifferent, since it pushes its adventurous growths into the dense shade of every other plant that it is able to reach. The branches do not seem to root naturally, but they will do so at the invitation of a hair-pin, and the plant strikes readily from cuttings. It seems odd that a rock garden shrub of such obvious charm and ease of culture should still be so uncommon that one rarely sees it in the lists. *North Wales.*

ORCHID NOTES AND GLEANINGS.

EPIDENDRUM ENDRESII.

PLANTS of this dainty species are now developing flower buds at the apices of the new growths, and sufficient water will be needed at the roots to assist the expanding blooms, after which very little water should suffice to keep the roots healthy and the small, Reed-like growths in a plump condition. The chaste flowers keep in perfection for many weeks if care is taken to avoid any moisture collecting on the blooms.

Although Epidendrum Endresii is generally recommended as a cool house plant, it appears to thrive satisfactorily in a light position at the cooler end of the intermediate house, where it should be kept fairly dry at the roots for a few weeks after the flowers are removed, increasing the supply of moisture as fresh growth commences in the spring, when any necessary repotting may be done. For this, well drained receptacles and a compost of three-parts Osmunda fibre to one part Sphagnum-moss, adding broken charcoal or crushed crocks to keep it porous; over-potting should be avoided. The compost should be pressed firmly among the roots, so that water will quickly pass through, otherwise it will soon become spongy and likely to remain saturated for longer periods than is beneficial to the roots; decay quickly sets in under these conditions. Well-established plants require ample moisture at the roots during the growing season, allowing the compost to become fairly dry between each application.

Similar cultural conditions may be afforded the smaller and beautiful flowered E. spectabile, except that this species requires a more exposed position, where the sunlight can reach the whole of the plant and roots after the danger of scorching is passed; it also has rather less water at the roots. *W. G.*

INDOOR PLANTS.

ACACIA BAILEYANA.

THIS plant is one of the most beautiful in the genus, and thrives in the open in several of the exceptionally favoured gardens of Great Britain. In Sussex, it is only possible to grow it in sheltered corners for a few years; a severe frost, such as is experienced once or twice in a decade, either kills it outright or reduces it to a stump, which, although it may sprout into rapid growth during late summer, is the more likely for that reason to be killed the next winter.

While it must be considered unsatisfactory for outside culture in most localities, few plants are better suited for planting out in a winter garden, conservatory or corridor. Even if the temperature falls slightly below 32°, but only for a short period in the early morning, neither foliage nor flowers are in any way damaged.

It may be planted either as a standard or in bush form against a wall, but if in the latter position it should be allowed to spread forward, supported, perhaps, but not stiffly trained. Growing in any good, ordinary loam, its annual growths average from two to three feet in length, well clothed with bipinnate, silvery-blue foliage, which forms a beautiful setting for the golden-yellow blossoms.

A large standard, some fifteen feet in height and eighteen feet in width, growing in a cool house, from which frost is barely excluded, is well known to the writer. It flowers regularly each season, and the cut sprays form a welcome addition to decorative flowers in January. Under ordinary conditions the flowers last for several days, but in heated rooms soon wither.

After flowering the tree should be pruned, and as strong growths from hard wood do not flower satisfactorily the first season, it is good practice to cut back to a fork, saving the shorter branches, which extend during the following summer and form good flowering sprays.

Few plants give less trouble as regards insect pests. In mixed collections white scale sometimes appears on the older wood, but this is easily kept in check by spraying with a solution of nicotine or petroleum soap early in the year. Should the stiffer branches be inclined to press against the roof, a strip of sheet lead rolled around the stems will soon correct this tendency. According to Bailey's *Cyclopedia of Horticulture*, it is sometimes used in the more southern districts of the U.S.A. as a street tree. It is a native of New South Wales and Queensland. *J. Comber.*

ON HERBACEOUS BORDERS.

While not attempting anything of a detailed account of the general management, planting or upkeep of a herbaceous border, or yet to particularise on any one method to be adopted, it occurred to the writer, by virtue of the fact that the construction of new or renovation of existing borders may be under consideration, a few random notes and comments—gleaned from a close personal interest in this most fascinating branch of the profession—may not prove amiss, and possibly be of some assistance to those readers at present engaged in this particular work.

I will take the making of a new border, for after all the remaking is only a duplication of the making, except that the gardener is curtailed in the selection of site.

A herbaceous border, well planned and planted, is a particularly attractive feature of the garden, and can be made interesting and instructive throughout the spring, summer, autumn and, to a lesser degree, winter, while as a source of supply for the decoration of rooms, etc., it is practically unfailable. There are some who object to this "slaughtering" of their beloved subjects, but a discriminate use of the knife in the hands of an intelligent man would leave but little evidence of the "plundering."

The all-important question of site must of necessity be governed by the circumstances attending the particular border under construction, *i.e.*, the primary cause for its construction, the wishes of the employer, and a hundred and one other points that are sure to arise, and can only be met satisfactorily in each individual case. Certainly no form of gardening—at any rate, flower gardening—lends itself so readily, or has been subjected to such a variation of purposes, as the herbaceous border, for borders are to be seen occupying all sorts of positions and aspects. One may be set in turf, another with a background of some kind of evergreen hedge or wall; again, as a "set off" to the centre walks of the vegetable garden; while, on the other hand, they are found facing every point of the compass; in fact, one of the finest borders—in this case a series of borders—it has been my privilege to see, faced and sloped due north. Whatever the position chosen, it should be as open as possible, protected from the prevailing wind and clear of the drip of trees.

Personally, I consider the "ideal" border is one set in turf with an all-round approach, bordered by flags some eighteen inches in width, as this allows the dwarfer and more prostrate denizens at the front to overgrow the flags and break that tendency to "straightness" so often seen when the turf abuts the border. Again, to be thoroughly effective, a herbaceous border should have both breadth and length—twelve feet is none too wide, always provided the length is in proportion, and the environment lends itself to the dimensions—for it is only by a bold display that a true conception of the beauty of such a border can be realised. I well recall having to make an effective display with herbaceous subjects in a border backed by a terrace wall, and only some four feet in width. The result was not a success—it looked too puny and cramped. The attempt was eventually given up, and three definite subjects—Tulips, followed by Antirrhinums, and then Asters—were substituted, with a much more telling and gratifying result.

A good loam is the best medium for herbaceous borders, but by a judicious incorporation of manure and fertilisers any soil can be made suitable, always bearing in mind the somewhat cosmopolitan nature of the occupants. It may be found necessary—indeed, it is desirable—to specially prepare the sites for the choicer plants. There is one point I should like to emphasize—deep cultivation should be the keynote of the preparations. Where there is a sufficient depth of soil trenching should be carried out, breaking up the subsoil as the work proceeds. Should the latter prove unkind and of such a nature as to render trenching impracticable, bastard trenching should be adopted, taking care to incorporate a goodly dressing of suitable manure with the bottom spit, with a view to improving the texture and increasing the state of fertility.

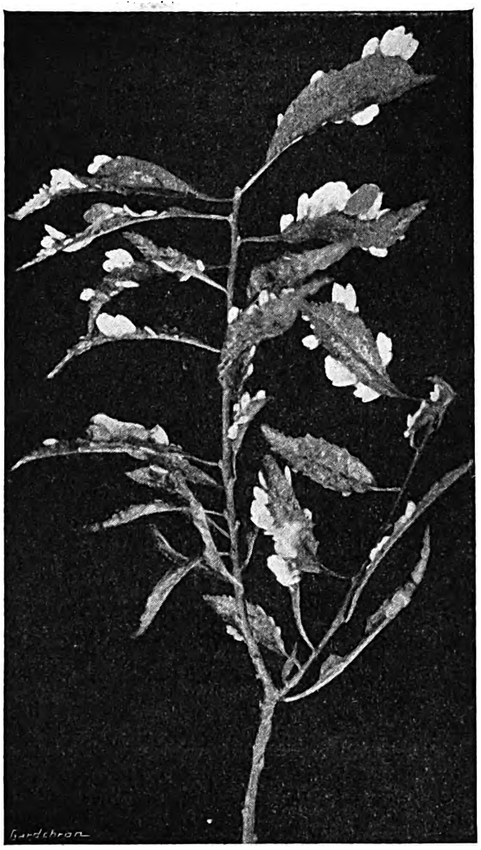

FIG. 213.—PRUNUS CERASIFERA VAR. HESSEI.
(see p. 468.)

Planting may commence so soon as practicable after digging has ceased, for at this season of the year climatic conditions play an all-important part, and it is advisable to push forward the work on all favourable occasions, endeavouring, if possible, to ensure the plants being comfortably settled and established in their new quarters before the advent of the really hard weather. There is much diversity of opinion as to the best time to plant a herbaceous border, viz., autumn or spring, particularly on heavy, clay soils; but I strongly advocate autumn planting, even although this entails the use of some drier planting medium—such as old potting compost—when planting in retentive soils.

It is impossible to treat of the arrangement of a herbaceous border in detail, this being a question of individual taste; but the stiff and formal method of "the tallest at the rear and the shortest in the front" is much to be deplored and discouraged. There is too much of the "prim and precise" atmosphere about it ever to appeal to the true student of unfettered nature. Rather should a suggestion of gentle undulations be the prevailing note—a bold group of tall subjects here, with one of slightly dwarfer stature running into it, and so on, until at the front one would get a group of plants, say, some nine inches to a foot in height, next to a carpeting subject—without any hint of sloping formality. On the other hand, the extreme should also be avoided. There should be no "shutting-out" of a dwarfer, and perhaps prettier group by planting a much taller one directly in front of it.

Two other points need, of necessity, to be taken into consideration—that of colour harmony and a due regard to the time of flowering of each respective group, to mitigate as much as possible the greatest bane of herbaceous borders—a blank period.

Just what to plant in such borders is best left to the discretion of those actually engaged in the work. No hard-and-fast rule can be laid down, as so much depends on the particular circumstances attending the construction of individual borders. Suffice it to state that a diligent perusal of any reliable plant catalogue will reveal a rich store of all classes of plants suitable for the purpose, and it is at this point that the expression "herbaceous" should not be taken too literally, for the ideal herbaceous border of to-day contains a discriminate and intelligent blending of not only strictly herbaceous subjects, but shrubs, alpines and bulbs; while the addition of suitable biennials and annuals, far from detracting from the general scheme, seems only to make this fascinating form of gardening "a thing of beauty and a joy for ever." *T. Wilson, Shugborough.*

FLOWER GARDEN.

DIGITALIS MARIANA.

While on a visit to the Royal Botanic Gardens, Kew, during the past summer, I noted in the herbaceous plant quarters an extremely handsome Foxglove labelled Digitalis Mariana, its country of origin being given as Spain. This Digitalis appeared a very desirable garden plant, but I have failed to find it listed in any seed or plant catalogue, so that it would appear not to be in general cultivation. Moreover, but very few horticultural works of reference contain any notice of it, and those that do, to my knowledge, deal with it very briefly.

The plants at Kew had large, dark grey, downy foliage which in itself was very handsome and the stout, downy stems bore massive spikes of large, creamy-white bells, the whole inflorescence being very striking and about three feet in height.

Bailey makes brief reference to it in *Cyclopedia of Horticulture*, and it is also described in Nicholson's *Dictionary of Gardening*, but, curiously enough, in both these authoritative works the colour of the flowers is given as rose. In the latter work it is described as a perennial, one-foot-and-a-half high, with ovate-oblong leaves, mostly radical and very downy on both sides, and rose-coloured flowers, the corolla being bearded on the lower part inside with long, white hairs, and marked with brownish-red spots.

If the plant seen at Kew, with creamy-white flowers, is not the true D. Mariana, it would be very interesting to know exactly what it is, as it appeared extremely effective—more so, I think, than if its flowers were rose-coloured—and also whether it is perennial or not and hardy in this country. *M. W.*

ALPINE GARDEN.

POLEMONIUM CONFERTUM.

There are two distinct groups of Polemoniums ; the first, tall-growing species, among which the most familiar is P. coeruleum, the old-fashioned Jacob's Ladder, and the second, dwarf species very suitable for growing on the rock garden, perhaps the best-known of these being P. reptans.

P. confertum is a lesser-known member of the latter group, and is certainly one of the most beautiful. It is a dwarf perennial, developing a woody, rhizomatous stock with age, the spreading rhizomes giving rise to tufts of small, sticky leaves with very diminutive leaflets crowded together to give a whorled effect. The foliage has a distinct musk odour and is, in itself, quite attractive.

The honey-scented, rich deep blue flowers of P. confertum are very striking, for they are borne in dense clusters on strong stems six inches or so high, the corollas being narrowly funnel-shaped and about an inch long.

P. confertum is a choice and comparatively rare species from the Rocky Mountains and Sierra Nevada, and is by no means so easy to grow as some of the better-known species. A warm position, shaded from the hottest sun, seems to suit it best, and it requires light, well-drained soil. During the summer, while in active growth, it relishes abundant underground moisture, but it is intolerant of winter wetness, and is liable to perish unless measures are taken to guard it from excessive moisture at this season of the year.

There is a variety of P. confertum known as var. mellitum, and sometimes classed as a distinct species, which has creamy-white flowers produced in a laxer, taller and more leafy inflorescence than that of the type. It has the same distribution as the true P. confertum, and although not so striking, is certainly well worth its place on the rock garden.

HOUSTONIA COERULEA.

By reason of its delicate daintiness and wonderful freedom of flowering, Houstonia coerulea should find favour with all lovers of alpine plants, and no rock garden with any claim to being such should be without it.

The genus Houstonia, which commemorates Dr. W. Houston, a plant collector in the West Indies and Mexico, comprises about twenty-five species, natives of North America, but few of which, however, appear to be in cultivation. Of those that are, H. coerulea is quite the most popular.

In America it is known by a variety of names, among others being Bluets, Innocence, Quaker Lady, Quaker Bonnets and Venus's Pride, all of which are complimentary to its appearance.

It forms dainty, spreading tufts, with small, opposite leaves, and commences its flowering season in May with a glorious display, continuing to flower in a lesser degree throughout the summer. The small, four-petalled flowers, borne singly on very slender stems up to three inches or so high, are of very dainty and charming appearance, being bright pale blue, varying somewhat in intensity of colouring and sometimes with a pinkish tinge, yellow-eyed, and fading paler after passing their prime. There is an attractive white-flowered variety offered by some nurserymen, and well worth a place, although it does not quite equal the type in charm.

H. coerulea is found naturally in meadows and grassy places, which would suggest it should prove a suitable subject for the alpine lawn. On the rock garden it delights in moderately rich but light soil containing small pieces of rock and surfaced with granite chips, with underground moisture throughout the summer but dryer conditions at the roots during the winter. It seems to prefer lime-free soil, and should be planted in positions shaded from the mid-day sun.

Houstonia serpyllifolia is frequently grown on rock gardens and is well worth its place, being slightly freer and taller in growth than H. coerulea and with a violet tinge to its blue flowers, while another not uncommon species is the coarser growing H. purpurea. *Kent.*

AETHIONEMA OPPOSITIFOLIUM.

This interesting Crucifer hails from the mountains of Asia Minor, and is deserving of greater notice than it apparently receives, for it is seldom seen even in the best collections of alpine plants.

It is of a sub-shrubby habit, from one inch to two inches high, forming a compact carpet of attractive glaucous foliage. The individual leaves are thick, smooth and entire, retaining their greyness nearly the whole year round. The flowers are white, suffused with a faint rosy-lilac tint, and are peculiarly attractive against the handsome foliage; even at the time of writing —mid-November—the buds that will give pleasure in May may be seen packed tightly between the terminal leaves.

Although perfectly hardy, this Aethionema delights in a warm, sunny, sheltered position preferably in a rock crevice ; given this, and an ample root run in good loam, it should require little further attention, increasing and proving attractive for at least nine months of the year.

It may be seen to even greater advantage when grown in the alpine house, for in the open the flowers are apt to be damaged by adverse weather. Grown in a fairly deep pan, in a compost of good fibrous loam (well broken but not sifted), coarse limestone chips, a little sharp sand, and one or two pieces of rock wedged firmly around the plant, it should be quite happy if not over-watered. Firm potting is essential.

Cuttings taken in July root easily in a closed frame in fine red sand, or in three-parts coarse silver sand to one of leaf soil passed through a fine-meshed sieve. The rooted cuttings should be ready to pot on into sixty-sized pots in about six weeks, using a compost of two parts loam, one of leaf-soil, and enough sharp sand to keep it open. Grown on in a cold frame they should make good flowering plants for the following year. *J. T. Wall.*

NOTES FROM WISLEY.

The recent heavy rains have hastened the fall of leaves from the deciduous trees and shrubs, so that now very little remains of the brilliant autumn tints which were a feature of the Wisley gardens a few weeks ago. Yet much remains to interest the keen student of nature, even at this drab season of the year.

Berried trees and shrubs there are in plenty—Rosa species, Pyracanthas, Cotoneasters, Barberries, and others—and this season the Holly trees and Thorns are laden with exceptionally heavy crops. It is during the winter months that the evergreen trees and shrubs prove their value as garden ornaments, the Conifers being of special interest; and Wisley is very well stocked with all these.

On the rock garden that gem of Primulas, P. Winteri—a large, long-established colony in the crevices of the big cliff on the margin of the main path along the top of the rock garden—is commencing to brave the winter with its exquisite, powdered, lavender blooms unfolding from the fat, meal-covered rosettes of foliage ; in fact, one plant is already practically in full bloom. It is unfortunate that some visitors to the gardens should abuse their privileges by removing such treasures as these, two of which have been taken during the past year, together with several other gems—Rhododendron repens, for instance.

Although, with the exception of Primula Winteri and Gentiana sino-ornata, which seems loathe to cease flowering, and an occasional out-of-season bloom on other subjects, no flowers are now visible on the rock garden, the various silvery-leaved alpines have a distinctly brightening effect, while the foliage of the invaluable Rhododendron obtusum var. amoenum is richly tinted with scarlet. The older leaves of a large carpet of Saxifraga Geum are also pleasingly tinted with red and orange which, in conjunction with the fresh green of the younger foliage, proves very effective. The alpine house has been set in order for its coming season and contains, with many other suitable subjects, a grand collection of Encrusted Saxifrages.

In the wild garden autumn colouring, in fiery shades of orange, still lingers on the various Vacciniums, and the pink-tinted inflorescences of Pieris japonica and P. floribunda, not, of course, open yet, are very attractive against the fresh green of the foliage, while Pernettya mucronata, so charmingly naturalised at Wisley, is carrying a wonderful crop of fruits, in many shades from pure white to deep crimson.

In Seven Acres there are numerous berried shrubs, especially notable among them at present being the small, yellow-fruited form of Pyracantha Rogersiana var. flava at one end of the large border, and Symphoricarpus racemosus var. laevigatus, near the pond, with striking clusters of white fruits freely borne. Cotoneaster rotundifolia and C. Simonsii are also fruiting well, the former being the most striking and having the added advantage that its fruits are not devoured so readily by birds as are those of C. Simonsii. In this portion of the gardens the numerous trees and shrubs with brightly coloured stems, the Birches, Willows and Cornus sanguinea, especially, are now coming into their own, while the fine specimen of Quercus coccinea, Knaphill variety, continues to retain its foliage, now rich Chestnut-brown in colour. Salvia officinalis var. purpurea and Senecio Greyii are attractive features, also Buddleia Fallowiana with its silvery stems and foliage. The several large trees of Cotoneaster frigida dotted about the gardens are all heavily laden with fruits, while the magnificent specimen of Cotoneaster horizontalis against the wall of the Laboratory is a glowing sheet of scarlet, so thickly are its branches set with fruits.

Naturally, in such an establishment as Wisley, the work of improving and developing is going forward continually, and throughout the past year much has been done in this respect.

In the recently laid-out flower trial garden the large rectangular lawn has been lengthened to make a splendid entrance from the Rose walk, and it now has a broad herbaceous border down each side, at the far end of each being a circular bed twenty-four feet in diameter.

Through the generosity of Mark Fenwick, Esq., the large alpine meadow adjoining the rock garden is being improved greatly by the introduction of large boulders of Sussex sandstone to give the appearance of natural outcrops of rock.

It is, however, at the northern end of the gardens that the greatest alterations have been made recently. The old experimental orchard has now been done away with and in its place a Lilac garden is being formed. All the land has been thoroughly trenched and already over one-hundred-and-fifty different sorts of Lilac have been planted, chiefly in groups of three, and it is hoped to enlarge the collection considerably during the near future. The undulating ground is intersected by broad, sweeping paths which were sown with grass in the early autumn, the main path down the centre being sixteen feet wide and terminating at the Pine plantation, through which it will probably be continued to link up with the broad walk through the so-called Pinetum. The Pine plantation has also been the scene of recent activities. Beds have been made beneath the Pines and planted with hybrid Rhododendrons, and the margin near the river is being devoted to Azaleas ; when finished, a very charming garden should result.

That the Pinetum will ever be a success is open to question ; certainly the majority of the Conifers in it are making but little headway. The broad, mown walk is a great improvement in this quarter, but the bridge across the public footpath is not so delighting to the eye, being very suggestive of the foot-bridges frequently seen spanning railways, canals, etc.

However, the work of developing Wisley—no mean task—is proceeding apace, and much of the work already in hand is of a sound, constructive nature, designed to be of lasting benefit to the gardens.

Finally, there is one task which would appear to be long overdue. I refer to the road leading to the gardens, which is in a shocking condition. True, the visitor with a luxuriously sprung car may not notice its defects, but the numerous pot-holes must be very trying to pedestrians and cyclists, and owners of small cars. Surely, with so much useful work going on inside the gardens, a little labour and expense might well be incurred to make the visitors' approach to the gardens a little less uncomfortable than it is at present. *F.*

PLANTS NEW OR NOTEWORTHY.

TRADESCANTIA REFLEXA.

The genus Tradescantia provides more desirable plants for the stove and greenhouse than for the open border. Few hardy species are found in gardens except T. virginiana and its numerous varieties. These seem to be favourite town plants as, when assisting as a judge in the Garden Competitions organised by one of our great daily papers, I found T. virginicana in many gardens, but it added little to their decoration.

T. reflexa is no stranger, but hitherto I had no opportunity of trying this species until the arrival of seeds from America in 1927. A few plants only were raised, and by a happy chance they were planted near a water tank, and the result was a very surprising one, as I had no idea anything hardy in this genus had any great merit. T. reflexa grew into fine, handsome specimens, as the illustration (Fig. 214) shows, only requiring a wet spot to proclaim itself a really good border plant of particularly elegant habit, and free-flowering to a degree.

It may be described as a three-feet-tall, branching, perennial plant with narrow, glabrous and glaucous leaves which reflex very gracefully; flowers, soft blue, in clusters of four to eight; the plant soon forms a large clump, and is only seen at its best in marshy or very wet ground. Where well grown, it is a far superior plant to T. virginiana, although the shade of blue may not be so fine. This species seems to have a wide range. Britten and Brown, in *The Flora of the Northern States and Canada*, mention that it is found from Ohio to Minnesota, in Florida and Texas. *T. H., Hyde Park.*

NERINE ATTAR, Hort.

This is a new colour-break among the garden section of Nerines, having a bright, clearly-defined, crimson keel running the whole length of the silvery segments.

N. pudica is now represented in most collections by garden forms, and the true N. pudica is rarely seen. It is one of the least conspicuous species in the genus, and carries a darker keel in the lower part of the flower. Some thirty years ago, I used it as a female parent for various garden forms, and found that its progeny bore very large flowers, so far as length of limb and span of flower were concerned, but had neither the compactness nor the breadth of segment of the crosses raised from the N. corusca types. It was one of these large-flowered but spidery hybrids which, crossed again with a garden form in 1907, produced N. Attar.

This variety carries a compact umbel of about ten flowers of medium size and of a faint silvery-blush ground colour, strikingly keeled throughout their length with a bright crimson (Fig. 209). In some flowers this keel is discontinuous in places. All parts of the flowers have a fine sparkle in a strong light. N. Attar is a slow grower, only bearing four leaves, and has thus far proved sterile, but flowers freely in November every year.

It is interesting to see the somewhat obscure keel of N. pudica come out so brilliantly in the second generation of crosses. But it is only one seedling out of many that shows this character in a marked way, and I think it is due to a dissociation of colour cells, a phenomena often noted in various plants, but difficult to explain. Such keels or stripes occur in various Amaryllids, such as the Placeas and Gastronemas. *A. Worsley, Isleworth.*

BULB GARDEN.

TULIPA CHRYSANTHA.

Tulipa chrysantha, so favourably written of by Mr. J. T. Wall (p. 424), promises to become a favourite with those who care for the many lovely species of Tulip now available. It comes from Kashmir, and, through the kindness and generosity of Mr. T. Hay, whose searches for good plants not in commerce have been of great value, I received some bulbs of it in the autumn of 1928. These were planted in a warm border, and the majority flowered last spring and were greatly appreciated. The bulbs were evidently collected ones, but the proportion which gave flowers was excellent. My plants did not vary in colour and were of a good clear yellow. They appeared to be taller than those observed by Mr. Wall and were about nine inches in height.

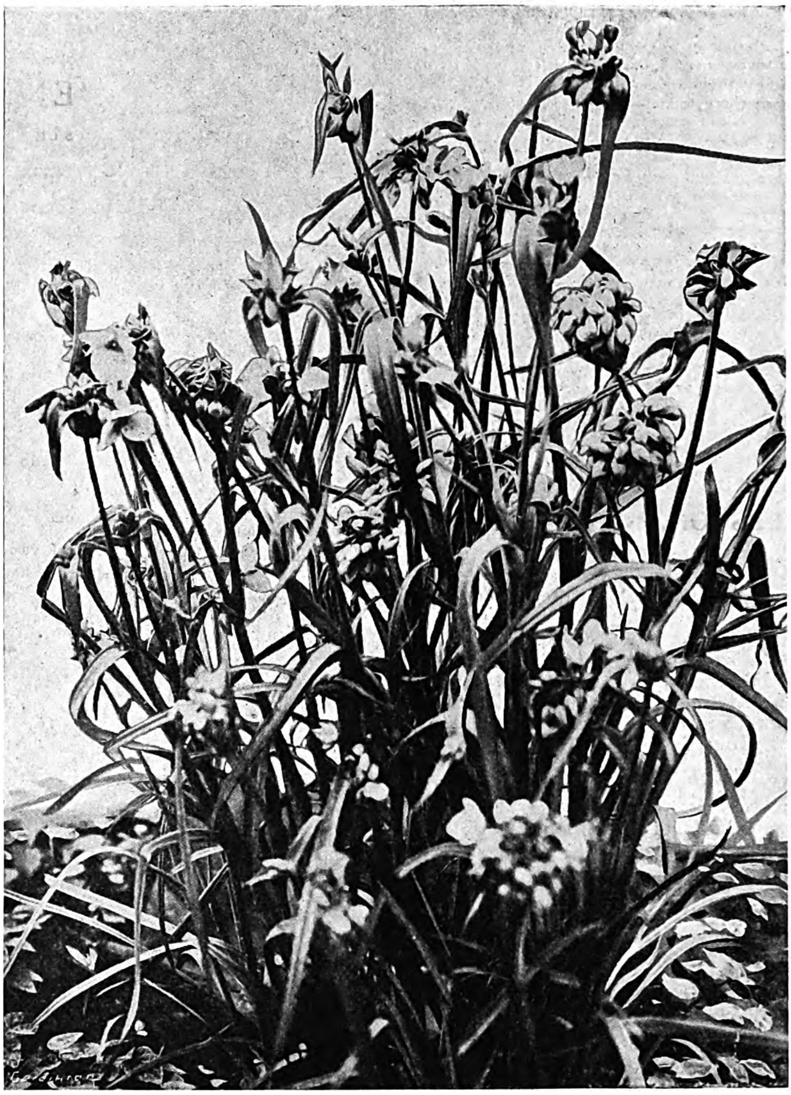

FIG. 214.—TRADESCANTIA REFLEXA.

T. chrysantha looks as if it would be of more value for out-of-door culture and leaving undisturbed than some of the Turkestan species. *S. Arnott.*

SCILLA PERUVIANA.

This fine old bulbous plant, which has been in cultivation here for over three hundred years, does not seem to have attained the popularity it deserves. A reputation for being only half-hardy may have stood in its way, but I feel confident that it is a great deal hardier than many more frequently seen. At any rate, I have grown it for many years in a dry border and a cool, deep loam and never lost a root. Last winter some old clumps, quite unprotected, withstood 30° of frost, and a few bulbs accidentally put on one side and left entirely exposed were so little injured that they grew away with vigour on being planted the following spring.

S. peruviana consists of a bulb about the size of a duck's egg, and an upright tuft of broad, strap-shaped, dark green, glossy leaves about eight inches in height. These bulbs increase rapidly by offsets and soon form a congested mass, which should be dug up every three years, the largest bulbs being replanted six inches or so apart. The flowers, which are borne on short, fleshy stems rather higher than the foliage, are carried erect in a bold pyramidal umbel. Individually, the blossoms are well over half-an-inch across, and the imposing inflorescence may be so much as six inches in diameter when fully developed. Although the typical colour of the flowers is a deep purplish-blue, there are varieties in a clearer blue, so well as a rosy-purple and a white. The flowering season extends over several weeks of early summer, and the plant asks no special attention. Give it a free loam, rather light but not too dry, see to the breaking-up of overgrown masses as soon as the leaves die down, which they do soon after flowering, and this Scilla should prosper.

The specific name of this plant suggests that it comes from Peru; the Kew *Hand List* gives Algeria as its place of origin, one gardening dictionary ascribes it vaguely to the "Mediterranean Region," another to Portugal, and in England I have heard it called the Cuban Lily, as well as the Peruvian Scilla! *J.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London: or by telephone to Temple Bar.* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXVIII.—UP THE DIBANG TO NIZAMGHAT.

On November 28, the Political Officer drove me out to Nizamghat, thirty-four miles due north of Sadiya, which is the shortest distance to the foot of the mountains. Nizamghat is an outpost on the Dibang, situated at the point where that river emerges from its gorge to spread over the plain. During the rainy season the road is closed to carts, as all bridges are carried away; in fact, it had only just been opened so far as Nizam when we went through—that is to say, the jungle cut back and the trestle bridges replaced. On all these bund roads across the plain, which, of course, are unmetalled dirt tracks, it is necessary to keep the track for bullock carts so far as possible separate from the motor road; otherwise the latter soon becomes impassable. It is also necessary to cut down and burn the jungle for some distance back on either side, to prevent trees from falling across and blocking the road, and also to allow the sun to get at the road and dry it up after rain. After the jungle has been cut back, during the next rainy season secondary jungle springs up, and soon reaches a height of twelve or fifteen feet; and this has to be cut down each year. What takes the place of the original jungle depends a good deal on circumstances.

Bananas come up in thousands on every clearing, and the road to Nizamghat is lined with them. In drier soil, various grasses take hold, and can never be eradicated; Saccharum sp., which grows on the chapri, is one of them. In the hills, abandoned cultivation is quickly covered with herbaceous plants—Compositae, Acanthaceae, Viola, Torenia, Polygonum, several Labiatae, and other universal weeds; followed gradually by a dense growth of shrubs and small trees. On the chapri, that is islands of sand and shingle formed by the rivers, the first and, perhaps, the only trees to establish themselves are Bombax malabaricum and Sterculia villosa. Probably in some places it all goes back to jungle; but it must take a long time.

The road from Sadiya to Nizamghat lies over apparently level ground, although the actual rise is about 300 feet. Much of the country about the Dibang is low-lying, and two miles out from Sadiya is the only area on the plain where wet Rice is cultivated. Several small rivers which flow to the Dibang, are crossed; but the Dibang itself hardly comes in sight until Nizam is reached. Ten miles from our destination, an immense tree lay across the road; however, with the help of coolies who were at work sawing it through, we cut a diversion through the jungle and just managed to get the car round. Nizamghat is, perhaps, the most picturesque outpost on the frontier (Fig. 216). A small clearing has been made on the high river bank, where the post stands—a stockade, held by twenty-five men of the Assam Rifles under a native officer. There are also a couple of "bashas" for officers on tour, or for travellers like myself. A small Mishmi village is hidden in the thickets close by and that is all there is of Nizamghat. The upper gorges of the Dibang are very formidable, and bar the way to ranges of almost inaccessible snow peaks, where a wonderful botanical harvest awaits discovery. Here dwell the lawless and degraded Chulikata Mishmis, although the country might be described as almost literally uninhabited; for all the use the scanty but hostile population would be to any expedition, even on the most modest scale, it certainly is!

As for the post, it is more of a gesture than for defence, and it is withdrawn during the rainy season. It serves to keep the Mishmis penned in their own beastly hills, except in so far as they come down to the plain on their lawful occasions. Just above the post, the Dibang comes zooming out of the hills (Fig. 217) and spreads itself in a network of channels over the gently sloping plain; but the hills keep a close grip on it and above Nizam the river is narrow and deep and icy cold.

From Nizamghat the Assam valley spreads out spaciously to the south and west, until lost in the mist. It is apparently a level plain right away to the Brahmaputra at Kobo, but the many rivers, even after leaving the hills still flow fast, and the slope is actually quite considerable, the plain rising over 300 feet in the thirty odd miles between Sadiya and Nizam. This may not sound very desperate, until one compares it with the gradient of the Brahmaputra, which falls only 600 feet in the 1,200 miles between Kobo and the Bay of Bengal!

Slight as the elevation is above the Sadiya plain, it has great advantages, for we were above the cold mist bath which lies so heavily over the Lohit during the winter nights. At six o'clock in the morning we looked down on to a chill grey ocean, while all around us the air was perfectly clear, a fine dew sparkling on the grass

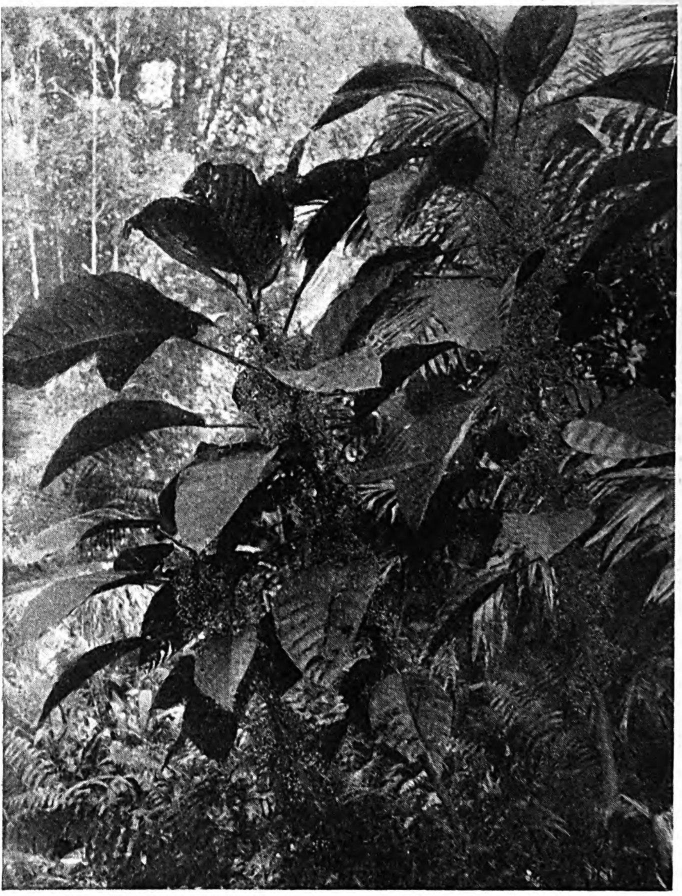

FIG. 215.—THE DANGEROUS "SURAT PAT."

Another thing which keeps the air clean and sweet is the boisterous wind which tears through these river gorges, throughout the night, and sometimes by day, too; although this continuous gale is apt to rasp one's nerves! Between Nizamghat and Pasighat I kept pretty close to the 1,000 feet contour all the way.

Two days spent at Nizamghat enabled me to climb the first low range of hills to about 3,000 feet, where there was a Chulikata village; but I found it rather bathos after the heights and delights of the Delei valley. Everywhere was thick jungle, although not quite so thick as on the plain. Cultivation is carried up to nearly 4,000 feet, and the fields were now gleaming with ripe Corn. There were very few flowers to be found, and nothing of great interest; but I collected what there was.

An interesting plant commonly met with in Upper Assam, along the edge of the jungle is called Surat Pat in Assamese—every resident knows it well by sight and reputation (Fig. 215):

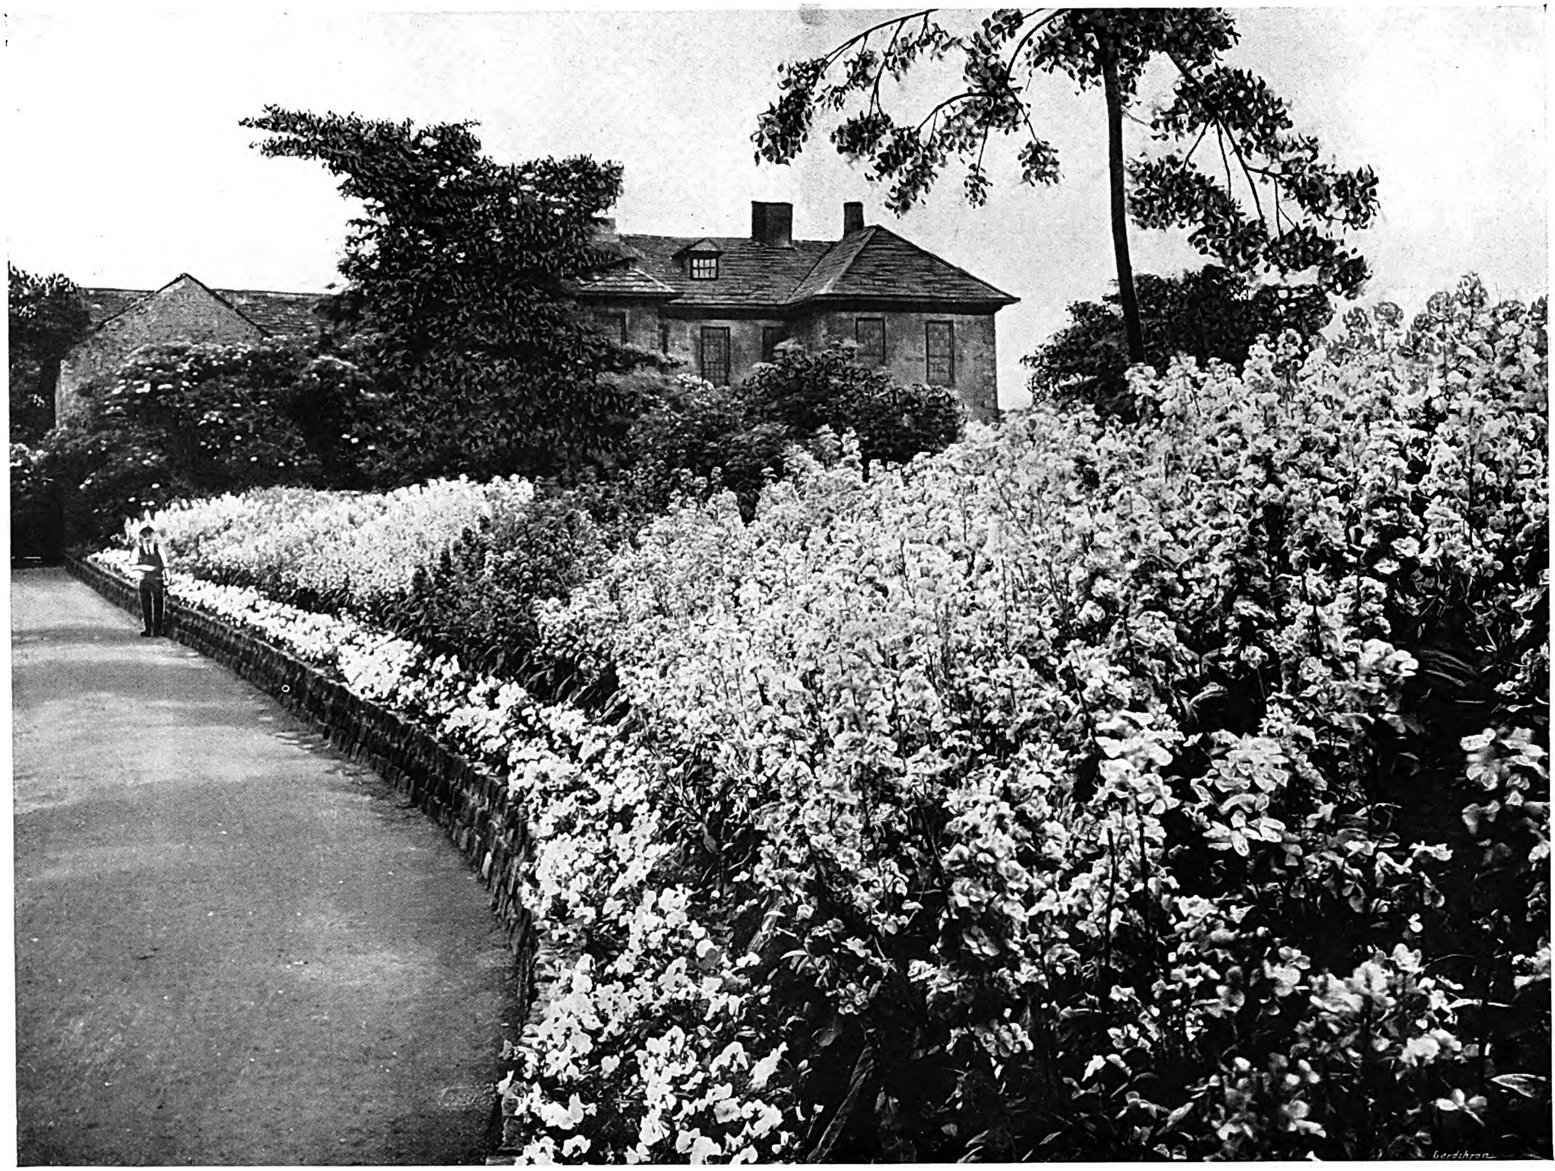
Supplement to THE GARDENERS' CHRONICLE.



BORDER OF STOCKS AT FOXDENTON PARK, CHADDERTON.

I do not know its botanical name, and as it was in fruit, am even doubtful about its affinities. It is a tall, loosely-knit shrub, with bunches of one-seeded white berries springing from the axils of large, dark green leaves. Looking through the leaves, one sees scattered translucent glands of great size, vesicles almost, which contain a powerful acid; but I could see no hairs on the leaves. The Abors boil and eat the berries. The plant, however, is notorious, not for its fruits, but for the fact that these harmless-looking leaves inflict a terrible sting on anyone rash enough to fondle them, the pain lasting so long as a week; I got stung on one finger, so I know! Doctors tell you that the only remedy is to bathe the injured parts in strong alkali; but apparently that has very little effect. Few people seem to know the native cure, which is to dig up the root, and rub the juice into the wound, when the pain is stated to go away within twenty-four hours. I did not try it; but then, I was only stung in one place, and there not badly.

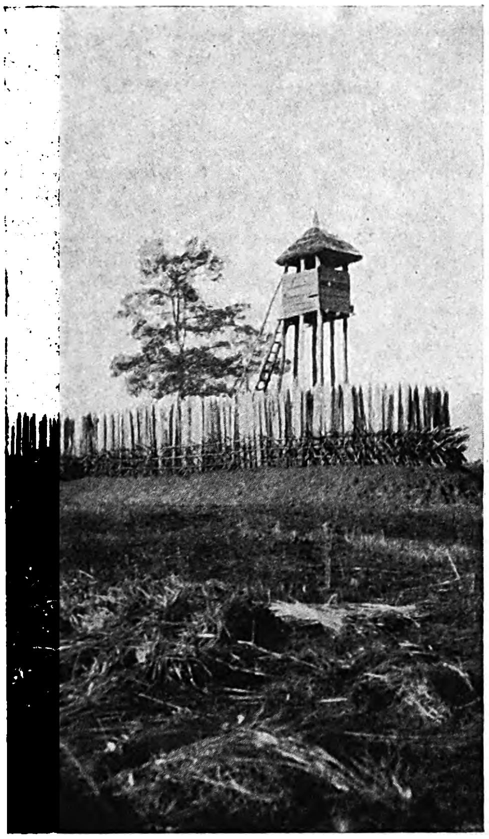


FIG. 216.—OUTPOST SENTRY BOX AT NIZAMGHAT

On December 1, I crossed the Dibang by canoe, having called up eight Abor coolies from the village of Dambuk, which was our destination; Nizamghat could not supply even that amount of transport. After crossing the river, we marched through miles and miles of cultivation which lay at the foot of the steep Abor Hills. Here and there we crossed a chapri, or a belt of jungle, but for six miles we walked between ripe crops of "dry" Rice, Job's Tears, Cotton and other things. The path was amply wide, sometimes between heavy Bamboo fences. Women and girls were at work in the fields, and occasionally we met men driving mithan. Approaching Dambuk, a village of four hundred houses built on rising ground at the very foot of the hills where a torrent bursts out of a slit, we crossed two stony beds, which, considering that they were perfectly dry, covered an immense area. The glare and heat here even in December suggested unutterable things in the hot weather, but a number of Duabanga trees (D. sonneratioides) were scattered over the stony desert, and looked perfectly at home.

I camped on the outskirts of Dambuk amid a grove of Jack-fruit trees, and, of course, came a good deal under observation from the inhabitants, who see a white man in their village only about once a year. The Abors of Dambuk have a reputation for being rather truculent, but as they pay poll tax in Sadiya they have to toe the line. They treated me quite well, but there was trouble in the air over an alleged epidemic in the next village. What the sickness was, nobody knew, although it sounded like diphtheria. Anyhow, the Dambuk Abors would not take me there, and I was warned that if I went on, I must not return to Dambuk this way, but must go on to Pasighat, and thence to Sadiya; from there I could return to Nizamghat, and so to Dambuk after seven days—if I liked. However, these quarantine regulations only affected me in so far as I took an Abor from Dambuk to act as guide and interpreter.

Of course, the Dambuk folk would not take me to the next village. They promised, however, that if I would stay a day, they would send a man to call coolies from the next village to meet me on the bank of the Sisseri river, and that they themselves would take me so far as the Sisseri. So I spent December 2 taking photographs and collecting a few plants.

All around the village there was a great area of secondary growth, mostly thick scrub, where a few Myrtaceae were in flower, and bushy Labiatae also. Paths ran in every direction. But on the plain below, and on the hills above, was dense jungle. *F. Kingdon Ward.*

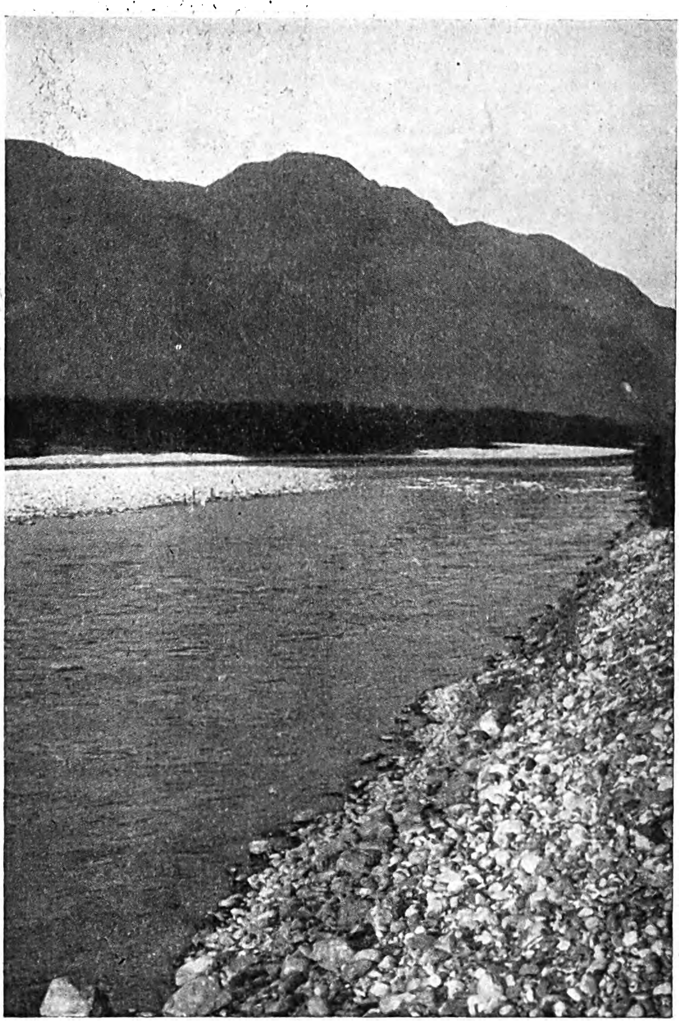

FIG. 217.—THE DIBANG EMERGING FROM THE HILLS.

PLANT VARIATIONS.

SPORTS, CHIMAERAS, VARIEGATION AND MUTATIONS.

(*Concluded from p.* 425.)

Variegation.

In its broadest sense, the term variegation is applied to plants in which two genetically distinct tissues of different chlorophyll character occur in the same plant. Numerous plants of this character have been described. In many cases, however, this variegation of the leaves is not caused by the presence of two distinct tissues in the plant, but is due to a variety of causes, the most important of which are:—

(a) Variegation, inherited, but due to physiological changes in the plant itself. In these cases a leaf may start white or yellow and become green or greenish, *e.g.*, Maize; or tissues may start greenish or yellow and become white, *e.g.*, Pelargonium zonale varieties Golden Brilliantissima and Mrs. Pollock; or the earlier leaves of a plant may be of one chlorophyll type, and the later leaves another.

(b) Mendelian variegations, of which there are several. In these cases the leaves may be irregularly mottled or mosaic, with differently characterised chlorophyll areas, as in variegated Tropaeolum; or the variegation may be more or less regular, as in the striped-leaved types of Maize. Such variegation is inherited in a Mendelian way, usually as a simple-recessive to green.

(c) Non-Mendelian variegation, where the variegation is transmitted by both the male and female parent. The appearance of green, white and variegated seedlings in the progeny of a green-leaved branch fertilised by pollen from a white-leaved branch, or a white-leaved branch by a green-branch, is thus due to a segregation of the dissimilar plastid contributions of the male and female parents at the somatic divisions.

(d) Variegation due to pathological causes which, although inherited by the mother plant, can also be transmitted by grafting, *e.g.*, Abutilon Thompsonii (Fig. 210). The variegation in Begonia manicata var. variegata (Fig. 211), Golden-leaved Laburnum, Jasminum officinale var. variegatum, and J. nudiflorum var. foliis aureis, etc., is probably of the same nature. This subject is very fully dealt with by Burbidge (*The Propagation and Improvement of Cultivated Plants*, p. 60).

A Brief Account of the Behaviour of Some Variegated Plants.

Innumerable species and varieties of plants have variegated leaves. A list is quite unnecessary. It is interesting, perhaps, to mention here that Sansevieria Laurentii (Fig. 212), a variegated leaved plant, when grown from a leaf, produces from its base a rhizome which later gives rise to a shoot producing normal leaves without the yellow margin.

Variegated-leaved plants having green, red, or yellow lobes of tissue distributed irregularly along the leaf margin sometimes occur in the following :—Abutilon Souvenir de Bonn, Coleus, some garden varieties ; Ficus radicans var. variegata, Hibiscus rosa-sinensis var. Cooperi, Hydrangea hortensis var. variegata, Leycesteria formosa var. variegata, Pelargonium zonale var. Golden Brilliantissima, Prunus cerasifera var. Hessei (Fig. 213).

Normal and Reversed Variegation.

Many plants have more than one form of variegation, *i.e.*, they frequently produce a form in which the position of the white or yellow portion of the leaf is reversed, *e.g.*, Ananas sativus var. variegatus (Pine Apple), the leaves of which have green centres and yellow margins. In Ananas sativus var. Porteanus, the leaves have yellow centres and green margins.

In Chlorophytum elatum var. variegatum (Fig. 218), the form having green centres and white margins to the leaf, gives green seedlings, while the form having white centres and green margins gives white seedlings (Collins, 1922).

Coprosma Baueri has two variegated forms, one with a creamy-white margin, and the other form, Stockii or picturatum, has a green margin with a creamy centre. Both varieties will sport to the green type.

Elaeagnus pungens, a green-leaved plant, produces two forms of variegation, viz. : var. aurea, with golden margins, and the variety Frederici (aureo-picta), with cream or pale yellow centres and green margins to the leaves.

The leaves of Euonymus japonicus var. albomarginatus have white margins and green centres ; E. J. var. aureus, green margin and yellow centre ; E. j. var. aureus marginatus, leaves mostly golden all over, margins mostly golden ; E. j. var. latifolius, green-leaved form ; E. j. var. l. aureus, yellow margins ; E. j. var. l. albomarginatus, white margins (Fig. 219) ; E. j. var. l. Duc d'Anjou, green margins, pale yellow centres (Fig. 219). At Merton, the variety Duc d'Anjou produces four distinct forms on one and the same plant, viz., (1) green-leaved shoots ; (2) white-leaved shoots ; (3) shoots having leaves with white margins (the variety albomarginatus) ; and (4) the typical form.

Hydrangea hortensis has several variegated forms, some with white or golden margins to the leaves, and at least one variety (nivalis) which has green margins and white centres.

Ilex Aquifolium (Holly) has many varieties with white or golden margins to the leaves, and some with green margins and white or golden centres, *e.g.*, vars. argentea-medio-picta, aurea-medio-picta and Lawsoniana.

Of Pelargonium zonale and P. peltatum, several of the white-margined forms (white skin over a green core) will produce shoots having a reverse form of variegation, *i.e.*, green margins with whitish or yellowish centres (green skin over a white core), *e.g.*, Caroline Schmidt, Snow Queen, Flower of Spring, and L'Elegante (Ivy-leaved).

Sedum Sieboldii var. variegatum exists in two forms, viz., white-edged and green-edged. Tradescantia fluminensis var. variegata (Fig. 220) has white-edged and green-edged forms.

Vinca major has green leaves. The variety variegata has white margins, and the variety elegantissima has green margins with a whitish centre, *i.e.*, green over white.

The inception and interpretation of much of the work mentioned above is due to the late Professor Bateson, Director of the John Innes Horticultural Institution (see Bibliography). I am indebted to Sir Daniel Hall, the present Director, for many valuable suggestions, to the proprietors of *The Gardeners' Chronicle* for the use of many of the illustrations and also to Mr. H. C. Osterstock of this Institution for many photographs.

THE GENUS PRIMULA.

(*Continued from p.* 450.)

TANGUTICA (Pax). Tawny P.
(Nivales).

A HANDSOME, smooth, non-mealy, perennial species with a tuft or rosette of nearly stalkless, oblong or oval-oblong, pointed leaves, slightly narrowed towards the base, two to three inches long and three-quarters- to one-and-a-half inch wide ; margins nearly entire or finely toothed. Flower stem smooth, twelve to fifteen inches tall, bearing several superposed umbels of four to six tawny, purple blossoms, on stalks three-quarters- to one-and-a-quarter inch long. Corolla about three-quarters-of-an inch across, with narrow, linear lobes ; tube about three-quarters-of-an-inch long, equalling the calyx in length.

Grows in damp places on the mountains of Kansu, in north-western China.

Culture : As for P. Maximowiczii.

TANNERI (King). Tanner's P.
(Petiolaris-Roylei).

A beautiful perennial species from the eastern Himalayas, with a tuft of smooth, non-mealy leaves which have pointed, triangular blades about two inches long, heart-shaped at the base, on slender stalks slightly shorter than the blade, dilated and sheathing at the base; margins irregularly and sharply toothed. Flower stem slender, five to seven inches tall, bearing an umbel of two to eight pale violet blossoms. Corolla about five-eighths-of-an-inch across, with oval, very deeply notched lobes; tube slightly longer than the calyx, narrowly funnel-shaped, with a ring at the mouth.

This species is found in the Chumbi Valley, in the Sikkim Himalayas, at 9,000 to 12,000 feet above sea-level.

Culture: As for P. saxicola.

TANUPODA (Balf. f.). Long-podded P.
(Farinosae).

A minute, mealy, perennial species with a rosette of somewhat thick, narrowly oval, blunt leaves about three-quarters-of-an-inch long, of which measurement the winged stalk occupies about one half; the sub-cartilaginous margins are furnished with irregular, blunt teeth; both surfaces are dusted with fine meal. Flower stem about a quarter-of-an-inch tall, bearing an umbel of about five blossoms, the colour of which has not been recorded. Corolla about three-quarters-of-an-inch across, with egg-shaped, very deeply-notched and deeply divided segments; tube cylindrical, not ringed. Flowers in August. Not in cultivation.

Grows in the Kumaon Himalayas, in the Ralan Valley.

Culture: As for P. Prattii.

TAPEINA (Balf. f.). Tapestry P.
(Bullatae).

A dwarf, sub-shrubby species with a branched, woody rootstock densely clothed with the dry remains of previous seasons' foliage. It forms dense cushions from six to twenty-four inches across, of narrowly lance-shaped or oblong-lance-shaped, blunt leaves, one-and-a-half inch to two-and-a-half inches long, gradually tapering to narrowly-winged stalks about equalling the blade in length; margins almost entire; upper surface sparsely mealy or glandular pubescent; underside densely coated with white meal. Flower stem about one inch tall, mealy upwards or glandular pubescent, bearing an umbel of two to six white, orange-eyed blossoms, or occasionally rose with a yellow eye, borne on slender stalks about five-eighths-of-an-inch long, coated with white meal or glandular down. Corolla about five-eighths-of-an-inch across, with broadly heart-shaped, deeply notched lobes; tube about half-an-inch long, cylindrical, densely coated with white meal on the outside. Flowers in June.

Grows on dry, shady rocks and cliffs, usually on limestone formation, at and above Tsarong, in the Salween-Kiuchiang divide, south-eastern Tibet.

Culture: As for P. Dubernardiana.

TARAXACOIDES (Balf. f.). Dandelion-leaved P.
(Petiolaris-Sonchifolia).

A deciduous, perennial species with smooth, membranous leaves resembling some deeply-cut forms of the common Dandelion: they are about three inches in length, and well developed when the plant is in flower. The stout, sparsely mealy flower stem is one-and-a-half inch to three inches tall, and bears an umbel of eight to twelve violet blossoms about three-quarters-of-an-inch long, with broadly egg-shaped or rounded, shortly-toothed segments, and a tube about half-an-inch long, with a ring in the mouth.

Grows in clefts and on the surface of the rocks at Malong, in Yunnan, western China, at about 9,000 feet above sea-level.

Culture: Peat, loam and limestone chips, or a cleft in a limestone rock, in a cool, damp spot, should suit this species.

TENANA (Bonati). Pére Siméon Ten's P.
(Malvacea).

This beautiful plant, formerly known as P. blattariformis (Fr.) var. Duclouxii (Bonati) is now raised to the rank of a sub-species of P. blattariformis. The slender rootstock produces a tuft of oval leaves one inch to two inches long and three-quarters- to one-and-a-half inch wide, heart-shaped at the base, borne on slender, rounded stalks, covered with short, stiff hairs; margins very deeply divided into rounded lobes; both surfaces rough with short, stiff hairs. Flower stem rather slender, nine to twelve inches tall, rough, with short, stiff hairs and bearing a raceme of about a dozen deep rose, purple, or lilac-coloured blossoms on slender stalks a half- to three-quarters-of-an-inch long. Corolla five-eighths- to three-quarters-of-an-inch across, with egg-shaped lobes; tube cylindrical, about half-an-inch long.

Grows in shady places on the mountains at Makong, near Tong-Tchouan, in Yunnan, western China.

Culture: As for P. blattariformis.

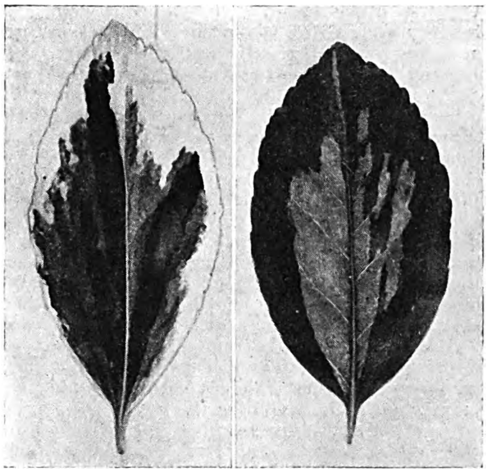

FIG. 219.—EUONYMUS JAPONICA.
Left, var. albo marginatus; right, var. Duc d'Anjou, yellow centre.
(see p. 468).

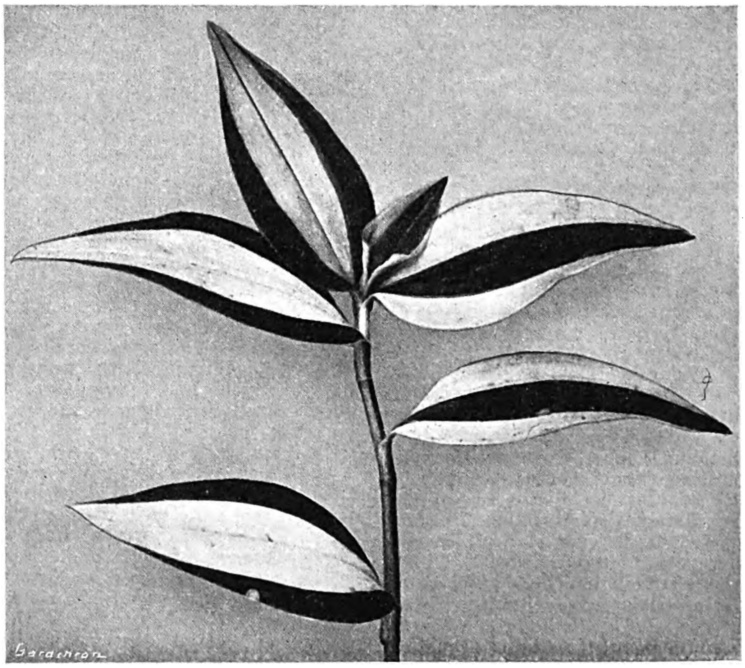

FIG. 220.—TRADESCANTIA FLUMINENSIS VAR. VARIEGATA.
Showing white margined and white centred leaves.
(see p. 468).

TENELLA (King). Dainty P.
(Obtusifolia).

A most delightful little Himalayan perennial species with a stout rootstock which produces tufts of egg-shaped or diamond-shaped, pointed leaves about half-an-inch long, narrowed to a wedge-shaped stalk; margins above the middle of the blade edged with coarse, rather blunt teeth; both surfaces more or less mealy. Flower stem very slender, one inch to two inches tall, bearing a solitary bluish-white blossom. Corolla about three-quarters-of-an-inch across, with five very broad and deeply notched, heart-shaped lobes; tube slender below, broadly funnel-shaped at the throat, several times longer than the calyx.

Grows in rocky soil at Pari, in the Chumbi Valley, between Sikkim and Bhutan, at about 13,000 feet above sea-level.

Culture: Friable loam, peat, limestone chips and sand, in a well-drained spot abundantly supplied with water when the plant is in growth, with protection from damp in winter, are the conditions suggested.

TENUILOBA (Hook. f.). Narrow-lobed P.
(Minutissima).

A minute, densely tufted perennial species, with rosettes of almost smooth, non-mealy leaves about a quarter-of-an-inch long, with egg-shaped, stemless blades rounded at the tip and slightly narrowed at the base; margins above the middle furnished with regular teeth. Flower stem obsolete; flowers nearly stalkless, sunk in the rosettes of foliage. Corolla purple, about three-quarters-of-an-inch across, with narrow, linear segments deeply cleft into narrow lobes; tube narrow, slender, cylindrical, slightly hairy, much longer than the calyx.

Grows in rocky soil near Yemutong, in the Sikkim Himalayas, at about 14,000 feet above sea-level.

Culture: As for P. tenella.

TIBETICA (Watt). Tibetian P.
(Farinosae).

This dwarf species usually dies after it has produced seeds, although it is perennial at times. The short rootstock produces a tuft of elliptic or oval-spathulate, blunt or pointed, leathery leaves about half-an-inch long, gradually tapering to a short stalk; margins quite entire; both surfaces smooth and non-mealy. Flower stem half-an-inch to three inches tall, bearing an umbel of one to five pale rose-purple or deep rose-coloured, yellow-eyed blossoms, on erect stalks one inch to two-and-a-half inches long. Corolla about five-eighths-of-an-inch across, with flat, deeply-cleft, heart-shaped lobes; tube about a quarter-of-an-inch long with a ring in the throat. Flowers from June to September. Introduced in 1915. *Bot. Mag.*, t. 8,796.

Grows in open bogs and damp, alpine pastures, in rocky soil in western and eastern Tibet, reaching an elevation of 17,000 feet above sea-level.

Culture: As for P. farinosa. *A. W. Darnell.*

(*To be continued*).

HOME CORRESPONDENCE.

The Need of Education for Gardeners.—I was much interested in Mr. Good's letter on this subject in your issue of November 23, also in Mr. Tullett's. To my mind, Mr. Good's letter practically answers Mr. Tullett's, for although private gardening is very poorly paid, and private gardens all over the country are being given up, there are many better paid jobs in these days—public appointments, not too badly paid, and with retiring pensions. I have conducted a correspondence coaching class for gardeners every winter for the last fifteen years, and this has brought me into touch with many men holding such appointments. Usually the R.H.S. General Examination is an incentive towards going on for the National Diploma in Horticulture; but with regard to the Diploma, many of us are feeling a bit dissatisfied with the practical examination at Wisley. If an eminently practical man, holding a public appointment entirely on his own merits, and in open competition with several other candidates, passes in the written N.D.H. and is turned down at Wisley on his own subject, practical work, does it not give food for thought? This is not one isolated case that I have quoted, but I have three men in my mind who were doubtful as to the written paper, but quite confident that the practical was "in their line." And yet they were turned down, and as a coach, one wonders what to say to these men on the fairness of examinations. *H. G. Kennedy-Bell.*

Primula crispa.—I am afraid Mr. Hay has made a mistake in his note on page 445 (December 7) of your journal, and I am not very surprised. With two such valid specific names as Primula crispa and Primula crispata so alike it must be easy to err in the correct naming of one or the other. From Mr. Hay's description of his plant, he has Primula crispata, which was collected in Sikkim by Mr. Cooper, and *not* the true P. crispa. Primula crispata belongs to the Capitatae section, has white farina on the flowers, and blooms in September, all agreeing with his plant. Primula crispa belongs to the Denticulata section, has yellow farina on the flowers, and blooms in April, and also comes from Sikkim. Both lack farina anywhere on the leaves. Farrer ought not to have grouped Primula crispa along with Primula capitata and its sub-species (much less so P. atrodentata !). I hope Mr. Hay will not mind my pointing out the error, as I feel sure he loathes growing a plant under its wrong name, just as I should do. *Ronald Smith, Greenhead, Gargrave, via Leeds, Yorkshire.*

Lonicera nitida.—It is important that both the merits and the shortcomings of Lonicera nitida should be generally appreciated, for not only is it easily propagated and reared, but it is also grown by the trade in large quantities. On account of these facts there is no reason why its price should be much in excess of that charged for oval-leafed Privet, so that if L. nitida can be proved to be a good hedging plant, there should be equal satisfaction on all sides. Varying experiences show very different results. I have planted L. nitida, one-and-a-half foot to two feet in height, on poor, chalky soil, and in a very exposed position at that, and within three years a perfect hedge four feet in height and eighteen inches through was formed. This hedge looked so well that it was transplanted *en bloc* to the local Chrysanthemum show and used in an exhibit, being returned in four days' time to its original position. It showed no resentment towards such treatment. Many thousands of plants of L. nitida have been used in this district, with excellent results where they were carefully planted and maintained. In the very worst south-west gales and during the most severe frosts it sheds a few leaves, but not sufficient in any way to detract from the appearance of a well-formed hedge. On the other hand, I have seen seemingly healthy plants in various parts of the country, standing perfectly still and becoming more bare at the base and more stunted in appearance as time goes on, thus presenting a miserable advertisement for the qualities of the plant. How can the difference be explained? The answer is, I think, quite simple. Lonicera nitida is, like other naturally vigorous hedge plants, a very gross feeder, and has a very extensive rooting system, surprisingly evident in the early stages of growth. In my experience, young plants not more than twelve to eighteen inches in height, which have been at least once transplanted, put into suitable enriched soil, never look back, and if kept vigorous by means of annual mulching and frequent clipping between the months of May and August, keep growing until a height of four or five feet is reached. On the other hand, I have seen acres of nursery-grown stock which has stood on the same ground for two seasons without being transplanted, attaining a height of four feet or more, which, when lifted possessed roots as coarse as Carrots. When such specimens are planted as a hedge they drop most of their leaves, and unless they are cut back almost to the ground level, make practically no growth at all. In order to make a successful hedge, Lonicera nitida should be encouraged to maintain its vigour without a check of any kind. Until it is permanently planted it should be transplanted every year to keep the roots in a fibrous and growing condition. In addition, it should be fed liberally, for it will not maintain vigour on starved soil. The plants' success on chalky ground is attributed to the fact that humus in any form becomes quickly available in the presence of calcareous matter, and the plant is able to utilise the requisite raw material almost immediately. Autumn-rooted cuttings, whether they be in frames or in the open ground, should be moved the following spring and again the following autumn. Because a plant is easily grown there is no reason why it should be neglected in its minor requirements. Had L. nitida been difficult to propagate it would have been heralded with the pomp and splendour of an Osmanthus Delavayi, and would have, in common with most other evergreen hedging plants, been rendered the treatment and given the price attributed to the Yew or Cupressus Lawsoniana. If L. nitida is sufficiently transplanted, and is afforded the just amount of nourishment which its natural vigour demands, there should be little chance of failure. Hardiness is a dangerous subject upon which to embark. I have lost plants of various species of Cistus, Ceanothus and Escallonia when L. nitida has passed practically unscathed, and have certainly never lost a plant of the latter through frost. My own experience with L. nitida in actual cultivation and in hedge-making has been confined to chalky loam, where the plant has always been a success. The remainder of these notes are based on careful observation of the failure of badly-grown nursery stock as compared with the success following the use of well-transplanted young plants. *N. Catchpole, Brighton.*

——My recent article on Lonicera nitida (p. 322) was based upon observations of the plant in widely separated parts of the country. These observations have indicated that the behaviour of the species is erratic, and while I know of plants which are quite happy in high, exposed situations, I am also familiar with other specimens which are annually cut by frost, although planted in relatively sheltered gardens. In any case, a plant which is to be used for hedges must be reliable. I entirely agree with Mr. Chittenden (p. 391) that it would be of interest to collect information as to the response of L. nitida to varying conditions of soil and climate. *L. C.*

——Mr. Chittenden (p. 391) appears to have been unfortunate with Lonicera nitida, but even after reading of his doleful experience at Wisley, I am convined that failures with Lonicera nitida are rare. Since it was introduced hundreds of thousands have been distributed from here to all parts of the British Isles and no word of complaint has been received of its ill-doing, which must surely speak for itself; had it acted generally in the contrary manner which Mr. Chittenden suggests we should have been inundated with letters from disappointed growers, but, happily, it is quite the reverse. Of course, the non-success of a certain plant in one position, while it luxuriates in an apparently identical adjacent site, has always been a problem to gardeners, even to those who have grown very old in the lore. It would seem that the bad behaviour of L. nitida at Wisley is due to some local condition, but if we were to condemn a plant through a few isolated failures our gardens would be almost denuded. *H. A. P., Brampton. Hunts.*

Kniphofia Fireflame.—I regret to find that the sender of the Kniphofia Fireflame, which recently received an Award of Merit, was stated, in the report of the Wisley Trials (see p. 373), to have been sent by Messrs. Ruys. It came with two other varieties from Messrs. G. Lubbe, of Oegstgeest, Holland, and was raised by that firm. *Fred J. Chittenden, Wisley.*

Pineapples at Minley Manor.—One of the subjects grown well and made a speciality of at Minley Manor Garden, by the head gardener, Mr. H. Wright, is the Pineapple Smooth Cayenne. During but very little of the twelve months taken to "fruit" them, is any great amount of heat ever used; in fact throughout the summer months, until colder days arrive, they are grown in a cool frame outside, plunged to the rims of the pots in "tan" or rough peat, and kept close to the glass to ensure sturdiness of growth. Whenever suckers arise from the base of the older plants they are removed and rooted in a close propagating case. They are then "grown on" without a check, until they are in twelve-inch pots. When the time comes for them to produce flower spikes the rosette of leaves begins to lie open. The plants are then removed to a warm house for fruit-bearing. Again, the best results are obtained by means of plunging the pots rim-deep in tan as before. They are given a night temperature of not less than 65°, and the atmosphere of the house is kept in a high state of humidity by means of frequent damping down or syringing, as the weather may demand. Feeding with liquid manure is attended to right up to the time the flowers open, when it is suspended and a drier atmosphere maintained, with a slightly lower temperature. After the blossoming period has passed they are allowed a good growing atmosphere again until the fruits are ripe; these Pineapples average between seven and eight pounds each in weight. *W.*

Bees and Fruits.—Having the care of bees in these gardens, and previously, I was interested in your correspondent's observations (p. 309) regarding their attacks on fruits this season. I first noticed them doing such damage in 1926, in Suffolk, on the Peaches and Figs on walls, but I came to the conclusion it was the result of giving the bees too much work on late honey-gathering in that season. But this year it has been worse, I think, and besides not having much honey from the hives I lost the best of the fruits. The dry season this year has made a great difference to the bees. I noticed them working on the flowers in the early mornings, their attention being turned later in the day to the fruits. It may interest Mr. F. Akers, *re* his question regarding bees and wasps (370), to know I have destroyed well over one hundred wasp nests about here this year, and in May I destroyed forty-seven queens. This autumn it has been surprising to see the queens seeking winter quarters; the stoke-hole here being a trap for them—they get under the slates and the warmth brings them down into a window. We destroyed 114 queens in that manner during September and October. I also saw eighty-seven queens killed under the bark of an Elm tree which had blown down two years ago. The wasps did not trouble the bees on the fruit trees, for they worked on the foliage alone, leaving the fruits to the bees, whereas last year the wasps attacked the fruits, leaving only the skins, and not a bee was observed attacking the fruits. *S. J. Robbins, Cefn Park, Wrexham.*

AN EXAMPLE OF HIGH MORTALITY IN RHODODENDRONS.

In the autumn and winter of 1928, considerable losses occurred in hybrid Rhododendrons of the Pink Pearl type that had been grafted three to five years previously. Material was received by Mr. Holmes Smith, Adviser in Agricultural Botany at the Manchester University, and at his suggestion we have conducted an investigation into the cause of the disease. Facilities for investigation have been placed at our disposal by a leading firm of nurserymen.

The affected plants showed relatively enormous lesions extending upwards from the ground level, and exposing the wood. On the smaller branches of such plants the bark was bleached a silvery-white, and in many cases there occurred numerous minute, black dots which, on examination, were found to be either the pycnidia of the fungus Diplodina, or, more commonly, the acervuli of a species of Pestalotia (Pestalozzia). These fungi have been identified as Diplodina eurhododendri and Pestalotia macrotricha, respectively. They have also been found in blackened areas on the leaves. The possibility of the disease being due to these fungi was therefore suggested.

Pestalotia macrotricha has been isolated from the inner tissues of diseased plants with some frequency, along with a fungus producing only sclerotia; but inoculation experiments with all these fungi have shown that the Diplodina is entirely innocuous, and the other two are, at the most, only feeble wound parasites.

At the commencement of the investigation it was seen that the lesions on the stems of diseased plants were related to the position of the graft union, and attention was therefore directed to the method that had been employed in propagation. This was, in fact, "saddle" grafting, and examination of younger plants showed that in some cases stocks and scions of unequal thickness had been united, a temptation that this method offers. The union was necessarily imperfect and exposed tissue was offered to fungus invasion over a long period. Moreover, in extreme cases the ensuing growth was uncorrelative in character, and the plants were subjected to peculiar growth strains. These imperfect unions between stock and scion are, therefore, believed to be the initial cause of the lesions observed in older plants. Further, it had been the practice to place the graft union just below the surface of the soil, a position that not only causes the callus to remain soft, but which is extremely favourable to fungal activity. In this connection it may be mentioned that standard Rhododendrons in which the unions were away from the soil were unaffected by the disease.

As preventive measures, therefore, it is suggested:—

(1) That on no account should stocks be grafted with unequal scions.

(2) That, possibly, "side" grafting should be more frequently employed; and

(3) That in planting out, the graft union should be left well above the soil.

Incidentally, it may be mentioned that in the course of the investigation, the well-known preference shown by Rhododendrons for acid soils of high humic content was disclosed. *W. O. Howarth, M.Sc., and H. G. Chippindale, M.Sc., Botany Department, University of Manchester.*

MODERN GLASSHOUSES.

While recently inspecting some newly erected glasshouses, and having all their modern improvements pointed out to me by the very enthusiastic owner, a doubt crept into my mind as to whether the structures were so very much in advance of those erected half-a-century or more ago. But I duly noted and approved many of the points my friend put forward, for truly the houses were well built of good materials—buildings to gladden the heart of any gardener.

Yet the doubt remained, and on my return home I pulled down from my bookshelf an old volume called *Structural Gardening*, which contains exhaustive details and explanations as to the best type of house and fittings for varied purposes, and as I perused its pages I wondered yet more whether all our modern houses are as perfect as we think them.

Admittedly the houses of to-day are lighter and have better heating arrangements than in the past; yet they contain many of the faults of the old houses, and almost invariably lack the solidity of the various internal fittings.

Most houses to-day have more or less elaborate means of opening and closing ventilators, but I have yet to see an arrangement for raising and lowering a shelf to suit the height of different plants, and to avoid the wet and time-wasting job of watering from the top of a pair of insecure steps. Or, if this be impossible, surely a shelf could be devised to carry off the waste water to a convenient point instead of allowing it to descend anywhere.

Then take the stagings in plant-houses. How seldom (but for the handiness of the gardener in improvising with any material to hand) do we see adjustable staging? Yet surely it is obvious that a staging suitable for, say, Chrysanthemums, is ill-adapted for Cyclamens.

Again, in building fruit houses and forcing pits, how seldom is any provision made for allowing a wheel-barrow to enter at all, let alone easily; and, when one can get a barrow through, much damage to expensive Teak-wood door frames might be prevented by a metal covering where the posts are likely to be damaged, or even a covering of match-boarding, which could easily and cheaply be replaced when necessary.

Then there is the annoyance of pieces of gravel getting jammed under a door through the latter being hung too low instead of it being given more clearance and allowed to close on to a sill.

With span-roofed houses the great fault often is that where they contain centre staging the doors invariably face the end of the centre staging instead of opening directly into the gangways, when it would be possible to enter with a hand-barrow, thus saving a good deal of time when plants have to be moved in or out.

Water arrangements are often very inadequate. The old-fashioned tank under the staging has much to commend it, but something should be done to prevent the leakings of the plants overhead from entering, as experiments have often proved that several plant diseases are spread by contaminated water.

Shading is still more or less decided on the score of expense, but the builders of houses might at least provide some means of getting on to the roof of houses without so much risk as is often the case at the present time. Span-roofed houses are often built too close together to prevent a ladder being easily laid on the roof, but it ought not to be impossible to arrange matters so that such things as the replacement of blind cords could be done from the inside, through the top ventilators.

As to ventilating gear, why could it not be actuated from the outside instead of being, as is so often the case, very much in the way inside the house?

No doubt many will raise the objection that the changes I advocate are unsightly and would add to the cost, but I think that with a little care the former could be avoided, and by doing away with some of the unnecessary ornamental fittings, such as the fancy terminals on the gable ends, and so on, the cost need not be greatly increased, while the advantages are obvious.

This by no means exhausts the list of improvements required. For instance, a system of "wiring" fruit-houses which could be quickly dismantled when the house requires cleansing or when a shoot gets the wrong side of the wire, would prove a great boon, and a few experiments with a ventilating fan as to its possibilities for use in certain types of houses would be watched with much interest.

Horticultural builders do, I feel sure, give good value for money, but I fear that often their designers have little experience of actual gardening conditions to help them. But it ought not to be too much to expect that our great horticultural societies would be able to furnish data as to the advantage or disadvantage of any particular structure or fittings. *S. W. Ecnad.*

HEDGEROW FRUIT TREES.

One of the phases of fruit-growing which interests visitors to the counties of the west, where Apples and Pears are extensively cultivated for vintage purposes, is the ancient custom of planting fruit trees in the hedgerows. Judging from the healthy state and vigour of the trees and the regular crops they yield, credit is due to our predecessors for realising that as shelter and shade for cattle the planting of these fruit trees was just as practical, and at the same time more remunerative, than that of timber trees. Many of the oldest and finest specimens of Perry Pear trees are to be found growing in the hedges. These handsome trees have most probably witnessed over and over again the renewal of the hedges, and it is evident, if vigour and absence of decay is any criterion, that they will again see the planting of fresh boundaries.

Commercial growers know that certain market varieties of Pears are most profitable when grown as naturally-developed standard trees; such trees make the best material for hedge planting.

There are many miles of hedges in market fruit-growing districts where fruit trees would grow as healthfully from among the lower brushwood as any timber trees that now embellish them.

This method of planting fruit trees is not peculiar to the west country, for in Kent and Middlesex Damsons are planted on the outside of plantations and in the hedges as a protection from gales. A quantity of fruits is thus secured at the minimum cost of production. It is even possible to utilise better varieties of Plums.

An excellent cropper, and a Plum most suited for this purpose is Blaisdon Red. This strong-growing Plum is a Gloucestershire variety; it is remarkably resistant to silver-leaf and highly prized in the Vale of the Severn. Blaisdon Red is a most accommodating tree, and in the county of its origin it is found growing satisfactorily on many types of soils and in all conceivable situations. It is equally at home on the thin soils of the Forest of Dean or on the rich formation of the Severn Vale. One feels confident that a Plum like this, possessing the ability to adapt itself to such a variety of conditions, might be successfully planted in any part of the country.

Should any grower contemplate planting this variety he is advised to purchase stock direct from the Gloucestershire growers themselves, as there may possibly be some difficulty in obtaining it through the usual sources, and ensure that the trees are true to name.

It may be objected that fruit trees growing under such conditions are not a success; that this is not the case is proved by the existence of the good specimens so frequently seen in the western counties. However, much depends upon the variety chosen and the kind of tree selected for planting. Weak-growing varieties known to form poor standards are totally unsuitable for the purpose, and if used will be most disappointing. Free growers should be chosen, such as Bramley's Seedling Apple and Pitmaston Duchess Pear.

The cultural requirements, such as planting, pruning and spraying, are similar to those employed for trees growing in an orchard. *John Coombes, N.D.H., County Instructor, Gloucestershire.*

MARKET FRUIT GARDEN.

November, with 7·77 inches of rain, rather more than October of last year, was the wettest month in my district since November, 1926. Ponds, which had been very low all the summer, were quickly filled to the brim, and large areas of low-lying land were flooded. The chance of getting any planting done before Christmas is now very remote, but I have very little of this work to do. There are several blocks of worn-out trees to be grubbed, and a good many trees to be removed from the plantations to prevent overcrowding. Most of the latter have now had all the branches sawn off and the wood cleared away, so as to facilitate winter spraying. There is no hurry for the grubbing of the stems and roots, which can be done as time permits. There is a great deal of winter work to be accomplished and the time seems to be all too short for it. Spraying with tar-distillate wash has first claim on attention whenever conditions are suitable. Interruption by frost, rain, and wind generally makes this a protracted business, and it is not wise to miss any opportunity which occurs after the end of November. Pruning will be unusually heavy, owing to the amount of growth produced as a result of last year's pruning and manuring. It would be a good thing if this could be finished before spraying, but that is quite impossible, as it occupies the more skilled hands all the time that can be spared up to the end of March and often later. The distribution of fertilisers will take some days, for this has to be done by hand. Finally, there are drains to repair, hedges to trim, and ditches to clean. Fortunately, digging is a thing of the past. I manage without this root-destroying operation even among bush fruits, and they are all the better for the omission.

Pruning.

Pruning is now a very different operation from what it was last winter. Then many of the trees were in very low condition, and everything was done to induce them to make growth. Spurs were thinned out and worn-out branches cut back severely to points where there seemed to be signs of greater vitality. This winter, pruning is concerned mainly with the young shoots, a much more enjoyable business. Last year's hard pruning, in conjunction with manuring, certainly proved successful in producing growth—too much of it in some cases. Now that I know that I can put vigour into the trees by manuring whenever it is necessary, I am not anxious to prune for growth. It seems to be a foolish business to force a lot of shoots every summer and cut them off each winter. Not only does this make a great deal of work, but the shoots crowd the tree and shade the fruits during the summer. I want to get back now to my old plan of merely thinning out in the case of all but the weakest growing varieties. Some trees which were not severely pruned last winter, because there was not time to deal with all of them, have not made anything approaching the same amount of shoot growth; but they have made plenty of fine fruit buds. That seems to me to be the ideal condition; the manures are utilised to make fruit buds instead of useless growth.

So long as mature trees show vigour in the leaf and form plenty of buds, what need is there of shoot extension? Trees in that condition may be manured every year without fear of getting them over-nitrogenous and so spoiling the quality of the fruits; and there may be some hope of getting them to bear annually. But it is not an easy matter to work back to this condition once pruning has produced a lot of shoots. I am trying to do it by leaving the leaders untipped and cutting unwanted laterals back to a fruit bud, where there is one, instead of spurring them in the ordinary way. The above remarks refer to Apples. In the case of Plums I do not mind how much growth is produced, within reason. Plenty of vigour is necessary for high productiveness in Plums; and there is not the same danger of spoiling the appearance and quality of the fruits that there is with Apples and Pears. However, Plums seldom receive any pruning beyond any necessary thinning out, because of the danger of introducing silver-leaf. They will, therefore, bear manuring on a more generous scale than Apples and Pears.

Red Spider.

Two dry summers in succession have greatly favoured the fruit tree red spider, which is different from the species found under glass. Growers everywhere are complaining that their trees are red with the eggs this winter. It is well-known that this pest has increased since the introduction of tar-distillate winter washes, which fail to destroy the eggs of red spider, but unfortunately do kill those of several insects which used to prey upon the red spiders and keep them under control. In my plantations, and in a good many others, the trouble is worst on Plums. On Apples, the insect is very largely controlled by the lime-sulphur wash used around blossoming time against scab. Plums do not receive this wash, and therefore the red spider increases without hindrance. It is the pre-blossom application of lime-sulphur that gives the best control on Apples, because the wash is then used at considerable strength, commonly one part in thirty. When this is applied at the pink bud stage of the bloom it catches the majority of the spiders when newly hatched. Any that hatch later are no doubt discouraged by the weaker post-blossom applications of lime-sulphur.

Unfortunately, lime-sulphur cannot be used so confidently on Plums. A pre-blossom application is almost useless, because Plums bloom early, before the red spiders have hatched; and the wash does not kill the eggs. After blossoming, Plums are liable to be injured by lime-sulphur at any greater strength than one in one hundred. I am informed on good authority that such a wash used ten days after the fall of the petals, and perhaps again five days later, will control the insects. I hope this may prove true; but it is the result of only one year's observation, and it stretches one's faith considerably. When the eggs are so numerous as they are this winter, something more drastic seems to be called for. There is another possible line of attack in the employment of the miscible oil washes which are now offered by several makers. These are largely used in America against the same pest, there called European red mite, and some favourable reports have been coming from users in this country. I made a small test myself two years ago, using one of these washes at five per cent. at the delayed dormant stage, and the control of red spider appeared to be excellent. It is unfortunate that these oil washes do not kill the eggs of aphis, so one does not escape the tar distillate spraying. The two applications will be costly; but I think they will pay if, as seems likely, there is to be widespread damage by red spider on Plums next summer. Where the pest is serious the leaves turn yellow and cease to function early in the season, greatly weakening the trees.

Winter Injury to Apples.

In one of my plantations of Apples, which slopes towards the south-west, a number of trees were injured by the exceptionally severe frosts of last winter. I did not find many with the bark of the stem split down, a form of frost damage which I have seen on previous occasions; but on many more the bark has died down one side—always the south or south-west side—without splitting. In some cases the dead area seems to have spread round the stem in the course of the season. Some of the worst of the trees have now been grubbed. The rest have been marked and will be watched; but I quite expect that a good many of them will not survive another summer. On hundreds of trees in this and other plantations there are small, dead areas of bark on stems and branches: but these are not extensive enough to matter.

Winter injury, although rare in this country, is quite common in America and very much dreaded. It was only recently that it occurred to me to look up this subject in American books. I find the particular form of injury mentioned above described exactly in *The Fundamentals of Fruit Production*, by Gardner, Bradford, and Hooker. It is called sunscald, and is a late winter injury to which all fruit trees and various forest trees are subject in America. Very small trees are rarely troubled, and trees old enough to develop thick scaly bark are less subject in the parts so protected. The description of the injury is as follows: "Attention is drawn to the injury by the dead and dry appearance of the bark on the south-west side of the trunk where the sun strikes strongest between noon and two o'clock. Sometimes the area is filled with a fermented fluid and the injury is called 'sour sap.' Later the bark may loosen and fall away, leaving an exposed area of dead sap wood. Many trees pruned to an open centre are affected at the crotch or even high on the south side of those scaffold limbs that lean to the north. In this last position the sun's rays are received nearly at right angles, and the injury there is in many cases very severe. The chief importance of this injury lies in its ultimate effects rather than its immediate results. It leads at once, obviously, to partial obstruction of conduction of nutrient and food materials; but of greater moment is the exposure to fungi and insects and the resultant mechanical weakening of the tree."

No remedies are suggested; so presumably there are none, but preventive measures are possible. The south-west side of the tree is subject to extremes of temperature during the winter. It may be protected from this, and particularly from the sudden thaw which does the greatest damage, by means of a stake or bundle of straw, or even by whitewashing.

It seems to me that this type of injury is much worse than the more familiar splitting of the bark. When that occurs one simply cuts away the lifted bark on either side of the split and applies paint or some other protective dressing to the exposed area. There is an unsightly wound for a long time; but I have never known such a tree to suffer. Bridge grafting is, I believe, sometimes practised as a means of rapidly healing the wound. Possibly the sunscald type of injury ought to be treated in a similar way, the affected area of bark being cut off so soon as it is seen. This should stop the trouble from spreading round the stem, as it seems to do in some cases. The death of the bark on one side of the stem will seldom kill a tree; but if it dies all round there can be no hope. *Market Grower.*

PUBLIC PARKS AND GARDENS.

Subject to the approval of the district valuer, Mill Hill Park is to be extended by the purchase of approximately one-and-three-quarters-of-an-acre of land between the Park and the Watford by-pass road, at a cost of £750.

It is recommended that the East Ham Town Council carry out various improvements at the parks and recreation grounds, at a total estimated cost of £7,011.

Subject to the approval of the Ministry of Health, the Croydon Borough Council has agreed to the purchase of land at Purley Way for playing fields.

The Hendon Urban District Council is considering offers by the National Playing Fields Association and the Carnegie Trust of grants amounting to £2,000 towards the acquisition of an open space near the Welsh Harp.

The Corporation of Stoke-on-Trent has passed a resolution to the effect that Dovedale should be created a national park and pledges itself to support in every possible way the efforts that are now being made to save Dovedale and its unique surroundings.

SOCIETIES.

ROYAL HORTICULTURAL.

December 10.—The last show of the year, which was held in the new Horticultural Hall, Westminster, was unexpectedly bright and attractive, and fairly well filled the large building. It was also noteworthy for the exceptionally high quality of many of the exhibits, and that six Gold Medals were recommended for different displays. Four of the Medals were for superb collections of Orchids, one was for a magnificent group of Begonia Gloire de Lorraine, and the other Gold Medal was for a large exhibit of dessert fruits. Orchids, of excellent quality, were so extensively shown that they would have made a show in themselves. Cypripediums of very many valuable sorts predominated, but there were also many good plants of Odontoglossum, Vanda, Calanthe and hybrids of Cattleya and Laelio-Cattleya. The Orchid Committee recommended two First Class Certificates and eight Awards of Merit to novelties; the latter were all to Cypripediums. Begonias, Chrysanthemums, Carnations and ornamental trees and shrubs were the chief floral features. The Floral Committee recommended four Awards of Merit to new Chrysanthemums. Beyond the large fruit exhibit, the Fruit and Vegetable Committee had no business of importance to transact.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart., (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. Frederick J. Hanbury, Prince Shimadzu, Mr. Lionel de Rothschild, Mr. Richard Thwaites, Mr. T. Armstrong, Mr. A. McBean, Mr. E. R. Ashton, Mr. Fred K. Sander, Mr. Robert Paterson, Mr. Clive Cookson, Mr. Charles H. Curtis, Mr. H. G. Alexander, Mr. W. Hatcher, Mr. A. Dye, Mr. J. E. Shill, Mr. S. Flory, Mr. H. H. Smith and Mr. J. Cowan.

First Class Certificates.

Miltonia Lydia, Stonehurst var. (*M. Princess Mary* × *M. Beau Brummel*).—A brilliant variety represented by a small plant carrying two flowers. Sepals and petals deep crimson that is quite fiery in sunlight; lip crimson-purple, paler near the base, and the reddish-brown mask is edged with white along the radiating lines, and has a few white or blush spots. Shown by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly.

Laelio-Cattleya Astroite (*Cattleya aurea* × *Laelio-Cattleya Istria*).—A very beautiful hybrid of good form and size. The sepals and petals are a lovely shade of lively pink with a yellowish underlay that appears in the centre and at the base. Lip deep yellow, edged with rose-purple and with a deep reddish-purple apex. Shown by Robert Paterson, Esq.

Awards of Merit.

Cypripedium Makeda, Stonehurst var. (*C. Charles Dillon* × *C. Cardinal Mercier*).—A bold variety that has very broad dorsal and ventral sepals, the former being somewhat contracted at the base. Dorsal sepal white, flushed with rose, heavily spotted with blackish-purple and stained with green at the base. Petals and lip green, shaded with brown, the former being edged with yellowish-green. Shown by Robert Paterson, Esq.

Cypripedium Baldovan (*C. Chloris* × *C. Nellie Pitt*).—In this hybrid the broad dorsal sepal is white, freely marked with soft purple and heavily stained with green at the base. The petals and lip are green and purplish-brown. Shown by Robert Paterson, Esq.

Cypripedium Vesper var. Virginia (*C. Vivid II* × *C. Alcibiades*).—This is a striking hybrid, flattish and well proportioned. The round, wide dorsal sepal is white, with a brown and green base that shades out to soft rose. Petals brown along the upper half, and yellowish-green on the lower half and at the apex. Lip brown, rimmed with yellow. Shown by Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bridge Hall Bury.

Cypripedium Miss Dorothy Sharp (*C. Cardinal Mercier* × *C. Nubia*).—A vigorous hybrid with a wide, white dorsal sepal flushed with rose, and heavily stained with green and blackish-purple at the base. Petals and lip soft brown and green. Shown by Sir William Cooke, Bart. (gr. Mr. H. Butcher), Wyld Court, Hampstead Norris.

Cypripedium Esther (*C. Selene* × *C. concolor*).—A pretty hybrid, with a broad, white dorsal sepal, stained with yellow at the base and also partly edged with yellow; petals and lip pale greenish-yellow. We can hardly reconcile the appearance of flower and foliage with the statement that C. concolor is one parent. Shown by Mrs. Carl Holmes (gr. Mr. W. J. Penton), The Node, Welwyn.

Cypripedium Mimosa var. Monarch (*C. Moonbeam* × *C. Christopher var. Grand Duke Nicholas*).—An attractive pale green form, with a broad margin of white on the dorsal sepal, and median lines of purplish-brown on the petals. Shown by Messrs. Cowan and Co.

Cypripedium Gerda (*C. Swallow* × *C. Garibaldi*).—A distinct, attractive and highly burnished hybrid, and well proportioned. The rounded dorsal sepal has a white margin around a large central greenish area that is heavily spotted with blackish-purple. The petals are green and brown with dark purple spots on the basal parts of the lower half; lip green, shaded with brown. Shown by Messrs. H. G. Alexander, Ltd.

Cypripedium Juliet var. magnificum (*C. Mulatto* × *C. Swallow*).—A beautiful Cypripedium with a white, purple-spotted dorsal sepal, yellowish-green and brown petals, spotted with purplish-brown, and a greenish-brown shaded lip. Shown by Messrs. H. G. Alexander, Ltd.

Groups.

Fred. J. Hanbury, Esq. (gr. Mr. S. Farnes), Brockhurst, East Grinstead, exhibited a very large group which was a splendid effort from a private garden. In the centre, Brasso-Laelio-Cattleya Ursula and Laelio-Cattleya Illustris were grouped with Cymbidiums, forms of Laelia anceps, Platyclinis Cobbiana and Masdevallia tovarensis. To right and left were Cypripediums in great variety backed by well-grown Odontoglossums and Vanda coerulea. We noticed pleasing examples of Stenoglottis longiflora, Lycaste Skinneri, Maxillaria picta, Restrepia striata, Miltonia vexillaria var. Leopoldii and Sophronitis grandiflora set among such good Cypripediums as C. Christopher, C. Reindeer, C. Goliath, C. Cyclops, C. Perseus, C. Stamperland, C. Midas, C. Lord Wolmer, C. Golden Fleece, C. Maudiae, C. Niobe and C. Monialis var. Hilda Sharp.

Another fine amateur's display was the superb group arranged by Robert Paterson, Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly. Vanda coerulea, beautiful Odontoglossums, Cymbidiums, Cattleya Imperial and Odontiodas were associated to form the central feature of this charmingly arranged display. Outstanding plants, set amid Cypripediums in extensive variety, were Laelio-Cattleya Schroderae var. Alpha, with fourteen flowers, and L.-C. Schroderae with a dozen handsome blooms; Dendrobium Coelogyne, Coelogyne Mooreana, Laelio-Cattleya Lucifer, L.-C. Golden Oriole, and Angraecum Eichlerianum. Oncidium varicosum var. Rogersii was used to form a graceful background, while the foreground and intervening spaces were filled with Cypripediums, all in the best of condition.

Cypripediums were shown splendidly, extensively and in great variety by Messrs. H. G. Alexander, Ltd. Moss and low Ferns were used to set off the well-grown plants, and Palms provided a background. A few of the outstanding kinds were C. Juliet, C. Cygnet, C. Corsair, Westonbirt var., C. Ballet Girl, with its white dorsal and ventral sepals; the deep hued C. Doris Stanton, C. Puffin var. Sultan, C. Baldur var. magnificum—of C. Fairrieanum parentage; C. Nydia, Westonbirt var., the well-named C. Golden Fleece, and C. Nidas, the big and bold C. Anak, C. Cairo, C. Mikado, C. Minotaur, Westonbirt var., and the handsome C. Lucifer.

Under the clock, Messrs. Charlesworth and Co. displayed Orchids beautifully, arranging a very fine group which had a large specimen of Cymbidium Doris as a centrepiece; this had eight spikes and a total of one-hundred-and-forty-nine flowers. Odontoglossums were a prominent feature of this group and included good spikes of O. Réve d'Or, O. Draco, O. crispum, O. c. var. xanthotes, O. Theckla, O. Fabia, O. Nada and O. Alva. Other fine things were Vanda coerulea, Oncidium Papilio, Coelogyne Mooreana, Cattleya Clotho, Potinara Camella, the curious Trichocentrum porphyrio, Miltonia Bleuana, Sophro-Laelio-Cattleya Alcon, the brilliant Odontioda Mossiae, O. Ruth, with seven large flowers, and Cycnoches pentadactylon.

S. G. Brown, Esq. (gr. Mr. Thurgood), Brownlands, Shepperton, contributed a very pretty group, lightly arranged, consisting of Vanda coerulea in good form; the lovely white Calanthe Harrisii, the brilliant C. Angela, Odontioda Zampa, O. Bradshawiae, Cymbidium Tracyanum, C. Hanburyanum, Odontoglossum Endymion, numerous Cypripediums and the interesting Gomeza planifolia, Lycaste costata, Vanda Amesiana, the old and sweetly-scented Maxillaria picta, and Cymbidium erythrostylum.

Lady Haddon (gr. Mr. O. Hayles), Rossway, Berkhampstead, showed a group of large plants of Cypripedium insigne, C. i. var. Sanderae, C. Ashburtoni, C. Leeanum and C. villosum, all freely flowered.

Messrs. Armstrong and Brown confined their efforts to a splendid display of fine Cypripediums—a battalion of them. A few that attracted our attention in this large collection were C. Warrior, C. Goliath, C. Memoria var. J. H. Walker, C. Icarus, C. Gwen Hanmer var. Phil, C. W. H. Page, C. Hya, C. Prince Albert, C. Nirvana, C. Golden Glory, C. Chrysostum var. Richard Fort, C. Makeda, and the heavily spotted C. Orbis. Messrs. Harry Dixon and Sons staged a few Cypripediums and Odontoglossums, the latter including good examples of O. crispum.

Messrs. Cowan and Co. made a special feature of Cypripediums arranged with a background of Oncidium varicosum var. Rogersii, O. boissyense and Cattleya Maggie Raphael. Leading Cypripediums were C. Lord Derby. C. Elatior, C. Mrs. Rickards var. Joyce Hanmer, C. Chesham, C. Regina Seymouriae, C. Maudiae var. magnificum, C. Ponticus, C. Nora and the very dark C. Chloe. Messrs. A. J. Keeling and Sons showed a small group of Orchids, chiefly Cypripediums, that included C. Greenjack, C. Mrs. Carl Holmes, C. Yeoman, C. Makeda of brilliant colouring, and C. Macaw var. magnificum.

Messrs. Sanders exhibited a large group wherein Cymbidium Tracyanum, C. giganteum and Phalaenopsis Rimestadiana were outstanding features. Cypripediums were included and shown in considerable variety, while Cattleya Mrs. James Watson, C. Eleanor var. alba and C. Bridal Veil were well shown. Along the front of this exhibit were Oncidium cheirophorum, Masdevallia tovarensis, Cypripedium niveum, Sophronitis cernua, Mormodes Buccinator, and Sarcanthus acutifolium. Cypripedium Big Ben, C. Euristopher, C. Yeoman, C. Edzell, C. Chesham, Langley var., C. Mrs. Carl Holmes, and C. Ranger, all with broad dorsal sepals. were conspicuous in the group arranged by Messrs. Black and Flory.

Notable sorts in the small collection of choice Orchids staged by Messrs. Stuart Low and Co. were Oncidioda Cora, Odontioda The Prince, Odontoglossum Miguelto and O. Amethyst; various beautiful Laelio-Cattleyas including L.-C. Nella, L.-C. Sladdenii and L.-C. Evadne; Brasso-Cattleya Nestor, B.-C. Denistor and B.-C. Juliet, and Cattleya Cooksonae. They also had grand specimens of the lovely white Coelogyne Mooreana, and the richly coloured Sophronitis grandiflora, and a choice collection of Cypripediums. Most noteworthy in the collection arranged by Mr. J. Evans were the floriferous specimens of Cypripedium insigne var. Sanderae, C. Maudiae, C. Vashtii and numerous others, and he also showed excellent Cymbidiums. In the display set up by Messrs. Sutton Bros. the numerous Cypripediums were the chief feature, their Cattleyas and allied Orchids also being very good.

The grand collection of Orchids set up by Messrs. J. and A. McBean contained many excellent specimen plants, notable among which were Cymbidium Doris, C. Orion, and an unnamed hybrid of rich colouring; a fine Odontioda hybrid; Brasso-Cattleya British Queen, Laelio-Cattleya Schröderae, Cattleya Imperial, several Cypripediums, including a lovely specimen of C. San-Actaeus, and the richly coloured Sophro-Laelio-Cattleya His Majesty, and S.-L.-C. Ramona. They also had a splendid plant of the small, rich orange-scarlet-flowered Epiphronitis Veitchii.

Mr. T. Bones staged large specimen plants of various Cypripediums, including C. Leeanum var. superbum, C. Wallisii, C. Leeanum var. roseum, C. Goliath, C. nitens and C. Athene var. pallens.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. G. W. Leak, Mr. A. E. Vasey, Mr. James B. Riding, Mr. Donald Allan, Mr. M. C. Allwood, Mr. B. R. Long, Major George Churcher, Mr. W. B. Gingell, Mr. R. Findlay, Mr. D. B. Crane, Mr. E. R. Janes and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. W. J. Bean, Miss E. Willmott, Mr. T. W. Taylor, Mr. A. Bedford, Mr. F. G. Preston, Mr. Reginald Cory, Mr. L. R. Russell, Mr. T. Hay, Mr. E. H. Wilding, Mr. C. Williams, Mr. G. Yeld, Sir William Lawrence, Bart., Mr. E. A. Bowles, Hon. Henry D. McLaren, Mr. W. G. Baker, Mr. Amos Perry, Mr. R. W. Wallace, Mr. R. C. Notcutt and Mr. N. K. Gould, Secretary.

Awards of Merit.

Chrysanthemum Kenneth Hastie.—See National Chrysanthemum Society's Awards in our issue of December 7, p. 455. Shown by Mr. H. Shoesmith, junr.

C. Balcombe Bronze.—Also see N.C.S. Awards, p. 455. Shown by Mr. A. G. Vinten.

C. Balcombe Sunray.—A small market Japanese variety of bright yellow colour, lightly stippled with chestnut. Shown by Mr. A. G. Vinten.

C. Thanksgiving Pink.—A valuable Japanese variety of good market type and size. The colour of the substantial flowers is a deep pink. Shown by Messrs. Keith Luxford and Co.

Groups.

Immediately inside the hall there was a splendid exhibit of Begonia Gloire de Lorraine, sent by Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex. The many plants were exceptionally well-grown and bore immense quantities of bright pink flowers. On a wall space there was also a good exhibit of the same variety of Begonia by E. G. Hulton, Esq. (gr. Mr. J. Dines), Downside, Leatherhead, which also illustrated exceedingly good cultivation.

Carnations were again well shown, and the blooms of Laddie in the several exhibits were of especially fine quality. In addition to an imposing stand of Laddie, Messrs. C. Engelmann, Ltd., staged Red Laddie, Topsy and Chintz of great merit. A vase of Wivelsfield Buttercup in the exhibit of Messrs. Allwood Bros. was of particularly rich colour, and they also included many blooms of Spectrum, Laddie and Harmony. Messrs. Stuart Low and Co. gave prominence to the deep rosy-cerise variety Countess of Harefield, and also had good vases of R. A. Nicholson, Kathleen, Thomas Ives and Eileen Low.

On a considerable floor space, Messrs. Walter Blom and Sons, Ltd., had an attractively arranged group of Azalea indica varieties, Begonia Gloire de Lorraine and Cyclamens, with very well-grown greenhouse Ferns in variety. The Azaleas predominated and these were low standards and bushes of considerable merit.

Chrysanthemums, mostly of the varieties of value for market sale, made a bright display of colour. Mr. A. G. Vinten had an extensive selection of well-grown flowers. His Japanese varieties included Golden Butterfly, Mayfield unrise, Sungold and Cheshunt White. Among the many good Singles were Mrs. J. Palmer, Mr. J. A. Burrell, Reginald Godfrey and Challenger. The Singles so well shown by Messrs. Keith Luxford and Co. included Challenger, Sunray, Absolute and Royal Red, while chief among the Japanese varieties were Friendly Rival, of rich golden colouring, Aurora, Enfield White, December Bronze and Balcombe Beauty.

An attractive group of hardy trees and shrubs, arranged by Messrs. L. R. Russell, Ltd., included large specimens of Griselinia macrophylla var. variegata, Cupressus Allumii and the narrow-leaved Myrtus Jenny Reitenbach. Messrs. Baggesens showed a number of useful Conifers in considerable variety. Those of golden colour included Thuya occidentalis var. Rheingold, Thuya o. var. lutea, Cupressus plumosa var. aurea and Juniperus japonica var. aurea. They also showed a good example of Libocedrus decurrens and upright Irish Junipers in a variety of sizes.

A number of interesting alpines and a miniature rock garden were shown by Mr. George E. P. Wood, who also staged small Conifers and a batch of Parochetus communis bearing its deep blue-coloured, Pea-like flowers. The Misses Hopkins made a miniature rock garden, in which they placed appropriate plants, and also showed vases of Jasminum nudicaule in flower.

Exhibits of paintings and garden sundries etc., were numerous. Messrs. Boulton and Paul, Ltd., erected a small glasshouse and garden frames; the Battle Steel Window Co. had ornamental metal gates, tubs, etc.; Messrs. Drew, Clark and Co. had a collection of ladders, and Messrs. Sanders and Co. and the Purbeckston Co. showed garden ornaments in stone.

A summerhouse of ornamental design was erected by Messrs. C. White, who also showed garden seats, wheel-barrows, etc., and the Neolite Works exhibited their special garden paving stones.

There were numerous other small exhibits of subjects pertaining to gardens and gardening, and several of jams and preserves.

Notable among the exhibits of paintings were the lovely collections of flower studies by Mr. E. A. Bowles and Mr. Frank Galsworthy, respectively. Miss Winifred Walker had an interesting collection of paintings of North American plants and the R.H.S. staged various *Botanical Magazine* paintings. Other exhibitors of paintings included Mrs. A. F. Compton, Miss Barbara Walkoff, Mrs. R. Boyle, Miss Kathleen H. Miller, Miss Joan Russell, Miss Winifred M. A. Brooke, Miss Edith A. Andrews, Miss M. Lilian Heish, Mrs. M. Townsend and Bain Garrard. Mr. Percy S. Cane showed garden designs.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. H. S. Rivers, Mr. J. Cheal, Mr. W. A. Divers, Mr. H. Markham, Mr. F. Jordan, Mr. A. Poupart, Mr. A. Bullock, Mr. J. Wilson, Mr. P. A. Tuckett, Mr. A. W. Metcalfe, Mr. G. F. Tinley, and Mr. A. N. Rawes, Secretary.

One new seedling Apple was shown before this Committee, but was not considered any advance on existing standard varieties. There were also numerous Apples for naming.

Groups.

A magnificent collection of fruits was staged by the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Aldenham, embracing grand bunches of Grapes, Apples in good condition, richly coloured and in great variety; Pears in variety, and Medlars. Grapes included Gros Maroc, Alicante, Cooper's Black, Appley Towers, Alnwick Seedling and Lady Downe's Seedling, while among Pears we noted the small-fruited Zéphirin Grégoire, Catillac, Basiner, Dr. Trousseau, Bergamotte Esperen, Uvedale's St. Germain, Beurré de Naghan and Glou Morceau. The Apples were exceptionally fine, especially the large dishes of King of Tompkins County, Hoary Morning, Blenheim Pippin, Newton Wonder, Emperor Alexander and Gascoyne's Scarlet, other sorts shown well including Lord Derby, Golden Noble, The Queen, Cox's Orange Pippin, Adams's Pearmain, Tyler's Kernel, Striped Beefing and Bramley's Seedling.

The following awards have been made to the undermentioned vegetables by the Council of the Royal Horticultural Society after trial at Wisley.

Cauliflowers.

Awards of Merit.

(6) *Early Six Weeks*, sent by Messrs. Barr and Sons; (78 to 93) *All the Year Round*, sent by Messrs. Hurst, Messrs. Zwaan and van der Molen, Messrs. Dobbie and Co., Ltd., Messrs. Daniels Bros., Messrs. James Kelway and Son, Messrs. Watkins and Simpson, Messrs. E. Webb and Sons, Messrs. Finney, Messrs. W. H. Simpson, Messrs. Clucas, Messrs. Cullen, Messrs. Nutting, Messrs. Dickson and Robinson, Messrs. R. H. Bath, Ltd., Messrs Barr and Sons, and Messrs. Harrison; (94) *All the Year Round Selected*, and (95) *All the Year Round, Driancourt's Stock*, by Messrs. James Carter and Co.; (96, 97), *All Seasons*, by Messrs. Harrison, and Messrs. Cooper Taber and Co., Ltd.; and (98-101) *Driancourt*, by Messrs. Nutting, Messrs. R. Veitch, Messrs. Morris, and Messrs. Speed (all alike). (107) *Danish Giant*, sent by Messrs. Zwaan and van der Molen. (124 and 125) *Reliance*, sent by Messrs. Dickson and Robinson and Messrs. R. H. Bath, Ltd.

Highly Commended.

(21) White Queen, sent by Messrs. Speed; (33) Primo, by Messrs. Zwaan and van der Molen; (68) Early Favourite, by Messrs. Barr and Sons; (110) Danish Giant, by Messrs. Hansen; and (137) Le Cerf, sent by Messrs. Zwaan and de Wiljes.

Commended.

(3) Early Dwarf Best of All, sent by Messrs. Barr and Son; (25) Snowball, by Messrs. Dobbie and Co., Ltd.; and (56) Mont Blanc, sent by Messrs. Clucas.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

At the meeting held on November 12, 1929, at the Town Hall, Manchester, in conjunction with the Chrysanthemum Show of the Royal Botanic Society of Manchester and Northern Counties, the members of Committee present were, Messrs. Henry Astley Bell (in the chair), A. Burns, A. Coningsby, J. Evans, W. J. Morgan, and H. Arthur (Secretary). Mr. A. E. Dale was invited to sit with the Committee.

First Class Certificates.

Cypripedium Trijo (*C. Antinous* × *C. Odin*): *C. Miss Queenie Dale* (*C. G. D. Nicholas* × *C. Eurybiades*); and *C. Arduco* (*C. G. D. Nicholas* × ?), all from A. E. Dale, Esq.

Award of Merit.

Cypripedium Mowghlii (*C. Pyramus* × *C. Becktoniae*). From A. E. Dale, Esq.

Cultural Certificates.

To Mr. J. Byram, for Odontoglossum grande and Cypripedium Goliath: and to Mr. A. Coningsby, for Laelio-Cattleya Ivanhoe var. Desdemona and L.-C. Schroderae.

Groups.

Mrs. Bruce and Miss Wrigley (gr. Mr. A. Burns), Bury, staged a Gold Medal group of Cypripediums in variety, among which were a number of home-raised seedlings. Mr. John Evans, Colwyn Bay, was also awarded a Gold Medal for a mixed group of Cattleyas and hybrids in variety, Cypripediums, Odontoglossums, Vanda coerulea and Oncidiums, the whole making a pleasing display.

Mr. D. McLeod, Chorlton-cum-Hardy, was awarded a Silver Medal for a small group of Cypripediums in variety; Hy. Astley Bell, Esq. (gr. Mr. Byrom), Garstang, staged Cypripediums and Odontoglossum percultum var. Mars and O. grande; Capt. W. Horridge (gr. Mr. Coningsby), Bury, showed hybrid

Cattleyas; and A. E. Dale, Esq., Wirral, and Messrs. A. J. Keeling and Sons showed Cypripediums.

At the meeting held on November 29, 1929, the members of Committee present were, Messrs. J. B. Adamson (in the chair), A. Burns, A. Coningsby, A. E. Dale, J. Evans, A. Keeling, W. J. Morgan and H. Arthur (Secretary).

First Class Certificates.

Cypripedium Buddha (*C. Christopher G. D. Nicholas* × *C. Warrior*); *C. Fad* (*C. Chrysostum* × ?); and *C. Eurystopher var. Daleii* (*C. Eurybiades* × *C. Christopher G. D. Nicholas*), all from A. E. Dale, Esq.

Cypripedium Vesper var. Virginia (*C. Vivid II* × *C. Alcibiades*). From Mrs. Bruce and Miss Wrigley.

Cypripedium Amazon var. Sultan (*C. Memoria var. F. M. Ogilvie var. Rex* × *C. Perseus*). From Captain W. Horridge.

Awards of Merit.

Cypripedium Amun Ra (*C. Gwen Hannen* × *C. Nirvana*); and *C. Genitor* (*C. Earl of Tankerville* × *C. Vashti*). From A. E. Dale, Esq.

Award of Appreciation.

Cypripedium Nepertiti (C. bingleyense × C. Alport Caesar). From A. E. Dale, Esq.

Botanical Certificate.

(First Class.)

Zygopetalum Wendlandii. From Messrs. A. J. Keeling and Sons.

Groups.

J. B. Adamson, Esq. (gr. Mr. J. Howes), Blackpool, staged a group to which a Silver-gilt Medal was awarded, showing Cypripedium Boltonii, C. Titan, C. Gurkha, C. Viking, C. Cavalier, West Point var., C. F. M. Ogilvie var. The Premier, C. beechense var. superbum, C. Thisbe, C. Stamperland, C. Draco, Westonbirt var., C. New Year, C. Everest, C. Alpha var. magnifica, C. Rosettii, and others, in grand condition.

A. E. Dale, Esq., Wirral, and Mrs. Bruce and Miss Wrigley showed Cypripediums in variety; Captain W. Horridge staged Cypripedium Louvain and C. insigne, Yellow var.; Messrs. A. J. Keeling and Sons, Bradford, showed Cypripedium Prince Albert, C. J. H. Walker, C. Leeanum, C. Gratrixiae; Odontioda Codeham var. grandis, with Barkeria spectabile. Mr. John Evans, Colwyn Bay, staged Miltonia William Pitt var.

The next meeting of this Society will be held at the Houldsworth Hall, 90, Deansgate, on December 20, 1929. The Committee will sit at 12 o'clock noon.

The meeting on January 10, 1930, is set apart for a special show, at which A. E. Dale, Esq., will present two prizes for the most meritorious displays, open to all members, and it is hoped that appreciation of this offer will be shown by a record meeting.

ROYAL CALEDONIAN HORTICULTURAL.

Mr. J. T. Jeffrey, Director of Parks, presided over a largely attended meeting of the above Society on December 3, when a lecture on "Chrysanthemums" was delivered by Mr. James Beats, Dundee.

The lecturer described the Chrysanthemum season, which was nearly at its end, as one of the finest ever experienced. From the beginning of August until the middle of November, early and early-winter sorts gave a superabundance of bloom, both outside and under the protection of frames that has seldom been equalled in Scotland, and the fine weather experienced during the months of September and October so built up the later varieties that finer displays of large Japanese varieties have never before been seen at the different Chrysanthemum Shows. In the opinion of Mr. Beats, the Chrysanthemum was undoubtedly our most popular, and certainly our most profitable, winter flower. For five months of the year it was the main source of the florist's cut flower supply. The plentiful supply of cuttings, the ease with which they can be propagated, their simplicity of culture and their free-blossoming propensities, without the expense of much artificial heat, and the long time they remain fresh after being cut, made them indispensable and one of the most profitable garden crops to grow, coming second only to Tomatos. The favourite type at the present time was partially disbudded. These are easily handled, growing nine to twelve blooms on every plant, firm, stout of stem and easily adapted for all kinds of room decoration.

Discussing the early-flowering outdoor Chrysanthemums, the lecturer advocated cleaning the roots when lifted by placing them under a water-tap so as to remove the eggs of slugs deposited at the base of the stem, after which they should be boxed and placed near the glass to promote sturdy cuttings. In his experience the best and quickest method of striking cuttings was to prepare a small bed near the hot-water pipes in an ordinary greenhouse with a temperature of 55°. Fill the bed with a mixture of half sand and half granulated peat or pulverised moss-litter, and insert the cuttings rather deeper than is usually done, and expose them to full light.

At the close of the lecture a long and interesting discussion was initiated by a question, "What is a Single Chrysanthemum?" Opinions differed in regard to the classification, but the majority of the speakers favoured the view that a single bloom had only one row of petals and all flowers with two or more rows should be regarded by judges as semi-double.

Prominent among the exhibits was a collection of fifteen varieties of Pears grown at Gordon Castle Gardens by Mr. Charles Webster, gardener to the Duke of Richmond, who had taken the trouble to describe the aspect of the wall, and the stock on which the fruits were grown, together with comments regarding fertility, quality, etc. Doyenné du Comice grown on a south-west wall on the Pear stock, was the best quality Pear in cultivation, but it was not a heavy cropper. Conference, on an espalier and on the Quince stock, was one of the best cropping sorts; while Marie Benoist on a south wall, and grown on the Quince stock, was a most regular bearer, but the quality was not always good. It required a warmer autumn than is usually experienced in Scotland. Marie Louise, on a south-west wall, fruited equally as well on the Quince as the Pear stock, when the former is double-grafted. Hacon's Incomparable was represented by fruits produced on Quince and Pear stocks, and the other varieties consisted of Durondeau, Alexandre Lambré, Beurré d'Avalon, Beurré Six, Doyenné Georges Bourcher (equal to Doyenné du Comice, but later), Passe Colmar, Beurré d'Arenberg, Blickling and Admiral Gervais (a fine cropper). The excellence of the exhibit was acknowledged by the award of a Silver Medal.

HARROGATE AND DISTRICT HORTICULTURAL.

The above Association held its third annual show of Chrysanthemums, etc., in the Winter Gardens, Harrogate, in late November. The show was very successful, close upon three hundred exhibits being staged.

In the class for eighteen Japanese Chrysanthemums, on boards, H. Hirst, Esq., gained the first place, also the N.C.S. Certificate, closely followed by J. Armitage, Esq., who, however, gained the prize for the premier bloom, a good specimen of Red Majestic. J. Armitage, Esq., showed the best six Japanese blooms, with H. Hirst, Esq., second. P. Cardwell, Esq., was successful in gaining first place for vases of Singles, Sir W. H. Ingleby being second; while the specimen plants again made a bold display, one exhibited by J. Armitage, Esq., having no fewer than 230 blooms.

In the fruit and vegetable classes, the Harrogate Hydro Co., Sir W. H. Ingleby, and Messrs. H. Young and J. Hawkes were the principal prize-winners; while the allotment holders also staged some very fine vegetables.

The Feldman Cup, awarded to the member gaining most points in the show, went to Mr. R. Jones, while Mr. J. H. Forth carried off the Shield presented by Councillor Mackay to the most successful allotment holder.

DERBYSHIRE HORTICULTURAL.

At the monthly meeting of the above Association, held at the Guild Hall, Derby, on the evening of December 2, Mr. J. Woodward, of Draycott, was awarded a Certificate of Merit and first prize for two dishes of Apples in the professional class, showing Gascoyne's Scarlet and Peasgood's Nonesuch; Mrs. E. S. Ayre (gr. Mr. G. E. Palfreyman), The Limes, Mickleover, was a close second, with Lane's Prince Albert and Allington Pippin.

In the amateur section, Mr. C. S. Buck, Derby, took the first prize and certificate for a dish of Apples, with Charles Ross. The fruits were afterwards sold in aid of the hospital funds.

Mr. W. H. Hanbury, of the Derby Education Committee, lectured on "Water in Relation to Plants," the lecture proving extremely interesting, and well illustrated with lantern slides.

Mr. J. H. Coley, Duffield, presided, and a very hearty vote of thanks was accorded the lecturer.

WIMBLEDON GARDENERS'.

On the evening of November 27, a meeting of this Society was held at Queen's Hall, Wimbledon, when Mr. H. Young, Vice-Chairman, presided over a somewhat smaller attendance than usual owing to the bad weather.

Mr. G. B. Begg, John Innes Horticultural Institution, lectured on "The Ideal Commercial Orchard." Every point connected with commercial fruit-growing was discussed. The grouping of trees with reference to full or partial self-fertility or sterility was dealt with thoroughly, together with the influence which insect pollenation would have upon them. Lists of trees were given which could be advantageously grouped according to the date and length of time of their blossoming period. Another important point was the proximity to a main line railway station, and to roads suitable for heavy traffic. Questions were asked at the conclusion of the lecture and suitably answered.

Mr. T. Price proposed a vote of thanks to Mr. Begg for his instructive lecture, and this was carried unanimously.

READING GARDENERS'.

The fortnightly meeting of this Association, held in the Abbey Hall, on Monday evening, December 2, was presided over by Mr. Frank E. Moring, the President, and there was a large attendance of members.

The lecture was on "Hardy Fruits," by Mr. M. Goddard, Bear Wood Gardens, Wokingham, who dealt with his subject in a most able and practical manner. He said that growers in England can grow, and do grow, the finest fruits in the world, although the variable climate in this country did at times make it a difficult problem. The subject of hardy fruits was an exceedingly broad one, and therefore he confined his remarks to a few of the best methods to adopt in the successful culture of Apples, Pears, Plums, Gooseberries and Currants.

A lengthy and animated discussion followed, and at the close a hearty vote of thanks was tendered to Mr. Goddard for his instructive and practical lecture.

There were some excellent vegetables staged in the various competitions. For three Parsnips (eight entries) the first prize was gained by Mr. J. Wynn, Hammonds Gardens, Checkendon; second, Mr. H. Goodchild, Queen Anne's School Gardens, Catersham; and third, by Mr. A. Manley, Highfield Park Gardens, Heckfield. For six Leeks (five entries), the first prize was won by Mr. W. Turnham, Greenlands Gardens, Henley-on-Thames; second, Mr. A. H. Dow, Sulhamstead House Gardens, and third, Mr. H. Goodchild. For twenty-five buttons of Brussels Sprouts (ten entries), Mr, W. Garnett, Calcot Grange Gardens, was awarded the first prize; Mr. H. Tuffin, Iris Court Gardens, Pangbourne, second; and Mr. J. Wynn, third.

In the non-competitive section, a First Class

Certificate was awarded to Mr. A. MANLEY, for some remarkably fine Poinsettias, the bracts measuring from fifteen to eighteen inches across and splendidly coloured. An Award of Merit was gained by Mr. R. G. TAYLOR, Plemont, Woodley, for three varieties of Brussels Sprouts. Rhododendrons were shown by Mr. F. G. RABBETTS, Bulmershe Gardens, Woodley, and Chrysanthemums by Mr. C. J. HOWLETT, The Yews, Earley.

SCOTTISH SEED AND NURSERY TRADE.

THE twelfth annual meeting of this Association was held in the Caledonian Hotel, Edinburgh, on December 4, Mr. David Bell presiding. Reference was made in the Nursery Section of the Report to the difficulties encountered by growers in their effort to stamp out mildew and other diseases in view of their prevalence in neighbouring private gardens. While nurseries are inspected by officials of the Department, little or no inspection is made of private gardens. The subject was brought before the notice of the Department of Agriculture, which pointed out that its Inspectors could not possibly cope with the work of inspecting all private gardens, but gave attention to any case brought before its notice. It was also reported that members having nurseries and trial grounds had received agricultural abatements under the de-rating Act, and so far as seed-cleaning premises are concerned, de-rating benefits had been given to them under the classification of "Industrial Subjects," with one notable exception in Glasgow, where the local Valuation Committee allowed an appeal by the Inland Revenue against the assessors, who proposed a grant of de-rating. In all other instances such appeals were dismissed, and the Court of Session has since upheld the view that the Inland Revenue was entitled to appeal by stated case to their court. It is therefore probable that the de-rating decision of the local Committees will be contested in future, and the Association has arranged that cases in which members are interested will be handled collectively, and the costs divided among those concerned in proportion to their respective rentals.

The accounts for the past year showed a credit balance of £151, and the following office-bearers were elected:—President, Mr. David Bell; Vice-President, Mr. William Cuthbertson; Representatives of Committee—Wholesale Section, Mr. Thomas Hogg (Messrs. Alex. Cross Seed Co., Ltd.), Glasgow; Horticultural Section, Mr. John Cairns (Messrs. Austin and McAslan), Glasgow; Agricultural Section, Mr. John Watt (Messrs. W. Drummond and Sons, Ltd.), Stirling; and Nursery Section, Mr. H. Stewart Paton (Messrs. Austin and McAslan), Glasgow.

At the dinner which followed, Lord Alness (Chief Justice Clerk) in proposing the toast of "The Scottish Seed and Nursery Trade Association," commented on the character of the duties undertaken and discharged by that body relating, as they did, to horticulture, agriculture and nurseries. He professed no knowledge of the technique of horticulture, but he said he did love a garden. He could remember a manse garden in the Highlands long years ago, an old-fashioned place with old-fashioned flowers—Polyanthuses, Paeonies and Pansies, Wallflowers, Mignonette, and London Pride. Now, after many years, he had the good fortune to possess a garden which was a source of perpetual happiness to him. When his Lordship lived in London, and now during his not infrequent visits there, he never failed when the chance presented itself to visit a flower show in Vincent Square, and he always felt a glow of pride when he noted, as he often did, that a Gold Medal or a first prize had been awarded—notwithstanding their ungrateful climate—to a Scottish exhibitor. It was a great thing to "subdue the English," and if the Scottish exhibitor did not always bring it off, the imported Scottish gardener not infrequently did.

The Chairman, Mr. Bell, in reply, recalled that Lord Alness, when Secretary for Scotland, had a good deal to do indirectly with the seed trade, as it was during his term of office that the Seeds Act was introduced, and they were indebted to him for the establishment of the Plant Breeding Station. He claimed that the trade had done its best to work up to the spirit of the Seeds Act, although it was impossible to work up to the letter of it.

Mr. James Elden proposed the toast of "Agriculture." Acknowledging the toast, Mr. Alexander McCallum, of the Department of Agriculture for Scotland, admitted that the state of agriculture was grievous in the extreme, but there were two points on which all people were agreed. These were: (1) That farmers ought to take steps to get a bigger share of the actual consuming price, and (2) it was obvious that the British farmer, if he is to make any advance against opposition, must make a reduction in costs of production, by which he meant increasing production, improving quality and eliminating waste.

Professor Wright Smith submitted the toast of "Horticulture," coupled with the name of Mr. William Cuthbertson, who submitted figures indicating that the estimated value of horticultural produce—fruits, vegetables, flowers and other home products, was equal to all that was grown in England. The area covered with glass was about four thousand acres, representing in value eight millions sterling, half of which he suggested was to be found in the Lea Valley.

The health of the Chairman was proposed by Mr. John Sutherland, Forestry Commissioner for Scotland.

Obituary.

Thomas Hall.—The death occurred at Highfield, Southampton, on November 26, of Mr. Thomas Hall, who for forty years was gardener at South Stoneham House, Swaythling; for ten years to Captain Davidson, and the remainder of the period to the first Lord and Lady Swaythling. Mr. Hall was in his eightieth year, and was well-known locally as a successful exhibitor of Grapes and hardy fruits, until his retirement in 1916. He did much to assist the local horticultural Society by organising fetes on its behalf at South Stoneham House. It was through his influence, too, the summer shows of the Society were held in the grounds, and were such a great success. The many beautiful wreaths received included some from Lord and Lady Swaythling and other members of the family, all tributes of the very high esteem in which Mr. Hall was held. The funeral was attended by many of the staff at Townhill Park, Bitterne.

Joseph Lowe, V.M.H.—The grand old man of the cut flower industry, Mr. Joseph Lowe, has passed away, full of years and honour. Born at Cookham in 1843, he went with his parents to Iver when three years old, and six years later he started work as a garden boy, as even his modest earnings were of material assistance in the upkeep of the family. Observant, shrewd and blessed with an excellent memory and a love for gardening he quickly put into practice the knowledge he gained. He made his home surroundings gay with plants and flowers, and secured a frame wherein to propagate his pets. He was eighteen years of age when he became under-gardener at Water Oakley, near Windsor, and a year afterwards entered the service of Mr. Charles Turner, the nurseryman, of Slough. Family affliction led him to return to his parents so that he might help them, and that spirit of generous helpfulness remained to ennoble his long life. In 1863 he commenced business as a jobbing gardener at Uxbridge, but soon found there were other and more lucrative openings in horticulture, therefore he began to build a nursery of his own in his spare time. The first flowers he sent to market were Roses, and the modest success obtained made him decide to devote his attention to the production of cut flowers for market. He worked like a Trojan, and for a time Mrs. Lowe looked after a little seed shop that he opened in Uxbridge. In 1867 he rented two acres of land and it was not long before the name of Joseph Lowe was famous in Covent Garden for the quality of the flowers he sent. Acre followed on acre, glasshouse on glasshouse, until by 1897 Mr. Lowe had built up a wonderful cut flower business; then his health broke down under the cumulative strain of many years. It was then that he took Mr. George Shawyer into partnership, and the combination—Messrs. Lowe and Shawyer, Uxbridge—has resulted in the construction and management of what is probably the largest establishment of its kind in the world. As a recognition of his great work in the cut flower trade, Mr. Lowe was awarded the Victoria Medal of Honour in Horticulture in 1923. A fine man and of striking appearance, Mr. Joseph Lowe was as good as he was clever. He was a deacon of the Congregational Church at Uxbridge, to which he became attached sixty years ago, and to which he remained loyal when commercial success had made him a well-to-do man. He was generous to all good causes, and also "did good by stealth and blushed to find it fame." Death occurred on Wednesday, December 4; the funeral took place at Hillingdon on the following Saturday, amid abundant evidence of the high esteem and deep affection in which Mr. Joseph Lowe was held. A portrait and appreciation of Mr. Lowe appeared in *The Gardeners' Chronicle* of February 24, 1923.

ANSWERS TO CORRESPONDENTS.

ARTIFICIAL MANURES FOR A MIXED ORCHARD.—*J. M.* Apply, so soon as possible, 6 cwts. to 8 cwts. per acre of basic slag, and 4 cwts. of sulphate of potash. In March, give 5 cwts. per acre of nitro-chalk. If this treatment is too expensive, give the nitro-chalk only. It is almost certainly nitrogen that the trees need; but it is wise to use a balanced dressing if possible. If there is a good response in the first year, the dressing of nitro-chalk could be cut down to 3 cwts. per acre for future use, and the sulphate of potash to 2 cwts. The dressing of slag should supply enough phosphates for three or four years.

CULTIVATION OF ASPIDISTRAS.—*K. T.* Aspidistras may be divided and repotted at almost any time. The end of March and beginning of April is, however, the best time, as growth is then becoming active, and the plants have all the season to get well established before winter. It is not advisable to divide them while there are any partially developed leaves, as they would thus receive a severe check. They grow in any ordinary garden soil, but a good compost for them consists of three parts good mellow loam and one of leaf-soil and clean, coarse sand; to every bushel of compost you could add one five-inch potful of bone-meal, or steamed bone-flour. Aspidistras do not, as a rule, require any feeding, although they may receive occasional doses of dilute soot-water, guano, or any other approved artificial fertiliser. The size of the pots will vary according to requirements, five-inch to seven- or eight-inch pots being required for large specimens.

NAMES OF FRUITS.—*B. C.* Your Apple appears to be an unnamed seedling; from your statements concerning it, it might well be worth looking after and a stock secured.

VIOLAS AND SWEET WILLIAMS DISEASED.—*W. F. A.* The Viola and Sweet William plants are both attacked by rust fungi, Puccinia violae and P. arenariae, respectively. Pick off and burn all foliage bearing "rusty" spots. Spray the plants now and again at intervals in the spring, with either a mixture of one ounce potassium permanganate and two ounces of soft soap in five pints of water, or with Bordeaux mixture. The wash should be applied to both surfaces of the foliage. Dress the ground in which the plants are growing now with a mixture of two parts superphosphate, two parts of fine bone-meal, and one part of sulphate of potash, applied at the rate of four ounces the square yard.

Wilt Disease of Carnations.

In certain parts of the country the ravages caused by Wilt Disease is causing the cultivators of Carnations very serious losses, and where this is the case they will turn with more than usual interest to Mr. H. L. White's account of the disease and its remedy.* The symptoms of Wilt Disease are so varied that growers are apt to believe that several different maladies are included under the name. The wilting Carnation plant may show a collar rot—a brown rot at soil level; or wilting may be gradual and progressive—in which case infection of the wood at the junction of the main stem and branch has occurred; or the shoot dies back when the infection originates in small shoots or in snags left in cutting blooms. In the propagation house the disease generally takes the form of foot diseases, infection having occurred at the surface of the cutting. Wilt Disease, at all events when it is accompanied by one of the "rots just described," is due to one or more species of soil fungi of the genus Fusarium. No fewer than five species of Fusarium have been isolated from Wilt diseased plants, viz., F. culmorum, F. anthophilum, F. acuminatum, F. herbarum and F. sporotrichoides. Of these the first four species are known already to be associated with disease of Cereals and pasture Grasses, and it has now been shown that the fifth species, F. sporotrichoides, gives rise to bud rot of Carnations. From observations made in a commercial nursery, Mr. White has satisfied himself that the disease may be but slight in the first year of planting, but that in spring or at the height of summer of the second year the Carnations may be badly attacked, and yet more so in subsequent years. Areas bared by the disease, when replanted, prove that the soil harbours the fungus parasite, for the new plants fall ready victims of Wilt Disease. Infection may come from air, water, and soil, and the disease is the more menacing in that the fungi causing it may exist in virgin soil. In general, however, infection takes place at a wound surface, for example, at the surface of a cutting. Therefore, cuttings should be made with a sharp knife in order that callus formation may be regular and complete. Or infection may take place at ground level, for example, if a cutting be inserted too deeply the fungus may enter through a dead leaf-base. Or again, in ramming soil about the roots when planting rooted cuttings the roots may be injured and the lesion serve as a port of entry of the fungus. Remedial measures must, of course, be based on a knowledge of the habits of parasite and host. Now the optimum temperature for the growth of spores of Fusarium is 67°F., whereas that for the growth of the Carnation is 65°F. Moreover, excessive humidity of soil and atmosphere favours the growth of the parasitic fungus, therefore the good cultivator, by keeping down temperature and moisture, will insure against the disease. But inasmuch as the parasite harbours in the soil it will be necessary in the case of a serious outbreak to resort to soil sterilisation. Mr. White remarks that, although chemical sterilising agents have so far given unsatisfactory results, steam sterilisation in the few cases in which it has been adopted has given entirely satisfactory results—not only by way of preventing the disease, but also in increasing the crop of Carnations. Pending, therefore, the breeding of strains of Carnations resistant to Wilt Disease, those whose Carnations are beset by this disease would do well to try steam sterilisation of the soil in which the plants are to be grown. Readers are also referred to an account of Wilt Disease of the Carnation, in our issue of September 28, p. 237.

Good Wishes.—The Proprietors of *The Gardeners' Chronicle*, together with the members of the Editorial and Publishing Staffs, offer heartiest good wishes for the Christmas season to all readers, contributors, correspondents and advertisers.

"The Gardeners' Chronicle" Almanac for 1930.—The preparation of our Almanac for 1930 is now proceeding, and as we are anxious to include so many dates of horticultural exhibitions and meetings as possible, the secretaries of horticultural, botanical and kindred societies are invited to send us the dates of their fixtures for the coming year, to reach us on or before December 31, 1929.

"The Gardeners' Chronicle" Medals, 1929.—*The Gardeners' Chronicle* Silver-gilt Medals have been awarded at various horticultural exhibitions to the following exhibitors during the year 1929:—Birmingham (Midland Daffodil), Mr. G. H. Furness, Berrow Manor, near Burnham, Somerset; Truro, Mr. James Allen, 35, River Street, Truro, Cornwall; Cheltenham, Mrs. C. V. Butler (gr. Mr. A. J. Collins), Twyning Park, near Tewkesbury; Colchester, Mr. C. W. Diggins, 47, East Hill, Colchester; Norwich (National Sweet Pea), Mr. W. Humphrey, The Loampits Gardens, Tonbridge, Kent; Guildford (Guildford Gardeners' Association), Mr. A. E. Tylecote, Mansard, Pilgrim's Way, Guildford; Northampton, Mr. J. Adams, 43, Cobden Street, Kettering; Dublin, Captain Lewis Riall (gr. Mr. Thomas Webster), Old Conna Hill, Bray, Co. Wicklow; Aberdeen, Mrs. Harper, Fernbank, Insch.; Shrewsbury, Lord Swaythling (gr. Mr. F. J. Rose), Townhill Park, Bitterne, Hampshire; Southport, Mr. T. L. Rushton, Garstang, Lancashire; Glasgow, Mr. John A. Grigor, The Woodlands, Banffshire; Dundee, Mr. David Smith, Lochee, Dundee; Edinburgh, Mr. Duncan A. Hill, 6, Bridge Street, Kelso; Taunton, Mr. M. Baker, Manor Road, Norton-Fitzwarren, Taunton; London (National Chrysanthemum), Mr. A. Robertson, 18, Abbey Road, St. John's Wood, N.W.8; Brighton, Earl Beatty (gr. Mr. A. Barrett), Reigate Priory, Reigate.

A Cactus-growers' Association in Germany.—Cactus-growing is on the increase in Germany, succulent plants becoming rapidly popularised among all classes of the community. In order to preserve their common interests and organise the trade generally, the chief Cactus-growers, headed by F. A. Haage, of Erfurt, have formed an association, of which the immediate objects will be to make a list of fixed prices (to be revised annually), to protect themselves against competition from various sources, the formation of a "black list," and to come to an agreement on the subject of nomenclature. Membership of the association is to be strictly confined to those growing Cacti commercially.

Scottish Potato Registration Trials.—The Department of Agriculture for Scotland announces the receipt of the report of the Potato Synonym Committee on the registration and immunity trials held recently at the Plant Breeding Station. The number of Potatos undergoing their first year's test as new varieties was eighty-four, an increase of thirty-four on the figure of the previous year, while there were fifteen varieties in their second test, and four varieties undergoing a final year's extended trial. Although the Committee has reported that three of the four varieties in the final year's trial do not, in their opinion, attain the required standard, they have recommended that the grower of the remaining variety, Dunbar Cavalier, should be given an opportunity of submitting a healthy stock for re-inclusion in the final trials in 1930 or 1931. The Committee was influenced in this decision by the fact that, while the variety showed considerable promise and the stocks in the country appeared to be healthy, that included in the trials was affected with virus disease. The Committee of Management which advised the Department regarding the trials has endorsed the recommendation, which has been accepted.

Cinchona Cultivation in the British Empire.—In a recent paper, entitled "Cinchona in the Empire: Progress and Prospects of its Cultivation" (*Empire Forestry Journal*, Vol. VIII, No. 1, 1929), Dr. J. M. Cowan, of the Indian Forest Service, discusses the present position with regard to the cultivation of the Cinchona, and its future prospects. The importance of the Cinchona tree, Cinchona Ledgeriana, as a source of quinine, is well-known, so that the cultivation of it on a large scale is a subject of national importance, especially when it is realised that quinine is the chief means by which malaria can be combated, and within the British Empire we have a large proportion of the malarial areas of the world. Previous to about 1880, the world's supply of Cinchona bark was secured from the native forests in Ecuador, Bolivia and Peru, but when supplies from these sources became unreliable it was realised that attempts would have to be made to grow the Cinchona tree elsewhere if a world shortage of quinine was to be guarded against. Consequently it was introduced to India and Java during the period 1854-64, and experiments in its cultivation were carried out also in Burma, Ceylon, Malaya, the Sudan, Jamaica, Trinidad, St. Helena, Mauritius, Australia and New Zealand, although in a number of these cases the attempts were not followed up to definite conclusions. In India, Cinchona growing is now confined to Government activities, and within the Empire India is the only country where the Cinchona tree is grown on a large scale. The bulk of the world supply, seventy per cent., is produced on the Dutch plantations in Java, India only producing four per cent. Only a very small quantity of Cinchona bark is now obtained from the South American forests. India produces only one-third of the actual amount required in the country itself and is, therefore, with the rest of the world, dependent upon Java for its supply. Dr. Cowan urges that an investigation should be carried out to find suitable additional land within the Empire for Cinchona cultivation, and also research in the matter of increasing the output per unit of area. He discusses in detail the problems which have governed the cultivation of Cinchona and the methods of growing and harvesting the crop, and urges that research is very necessary with a view to determining the best quinine-producing strains of Cinchona. Dr. Cowan's paper is an excellent summary of the present position with regard to Cinchona cultivation, a subject of such vital importance to a large section of the human race.

* "Wilt Disease of the Carnation," by H. L. White. *Fourteenth Annual Report*, 1928, Experimental and Research Station, Turner's Hill, Cheshunt, Herts.

Honours for Belgian Horticulturists. — A number of distinctions have been bestowed on some of the leading Belgian horticulturists, including that of Commander of the Order of Leopold, for M. Bauwens, Inspector-General at the Ministry of Agriculture, and M. Henry, the Director General; Commander of the Order of Leopold II, for M. Lambeau, President of the Brussels Tribunal of Commerce and of the Royal Linnean Society, etc. M. van Orshoven, Director of the Horticultural Office of the Ministry of Agriculture, has been created an Officer of the Order of Leopold.

Investigation into the Control of Rodents.—In connection with the investigations now being carried out at Oxford upon matters relating to the control of the various rodents which are a source of great annual loss to agriculturists, horticulturists and foresters, a leaflet has been circulated setting forth the type of damage done by the rodents, etc., and appealing for assistance from those interested in the making of observations and the keeping of records. Since the study of the fluctuations and control of numbers of rodents, such as voles, squirrels, rabbits, rats, etc., is inseparably connected with agriculture, horticulture and forestry, the co-operation of those associated with these professions in making certain observations and keeping records is of the greatest importance if successful work is to be accomplished in this direction. Anyone who is willing to help in this way, or who is interested in the subject, is requested to write for particulars to Mr. A. D. Middleton, University Museum, Oxford.

Gardens and the Queen's Institute of District Nursing.—The Duke of Portland writes, from 58, Victoria Street, S.W.1:—"The Queen's Institute of District Nursing, of which I have the honour to be President, desires me to ask your assistance to convey the gratitude of the Council to all those who gave valuable support this year to the National Gardens Scheme. His Majesty the King graciously allowed the Gardens at Sandringham to be opened, as in former years, and through the kindness of their owners, 690 other gardens were included in the National scheme this season. The result was that £7,765 was raised, which will be of the greatest assistance to the work of the Queen's Institute and the Nursing Associations throughout the country. The opportunity of viewing many of the most beautiful and interesting places in England and Wales has given great pleasure to garden lovers. In writing to those who opened their gardens last year, I expressed the hope that this year's result would be even more successful than last year, and I am happy to be able to state that this wish has been realised. I trust that the owners who have so kindly helped our cause in the past will do so again, and that owners of other gardens may be induced to take the same generous course. The gratitude of the Institute is tendered to the Press for their whole-hearted support, to the Railway Companies, to the Steam Ship Companies, and to the Travel Agencies, for displaying posters and for affording other means of publicity. Every endeavour will be used to make known so soon as possible the gardens which will be kindly opened during the ensuing year."

Big Pumpkins.—On p. 410 of our issue of November 23, *J. P.*, expressed the opinion that Pumpkins weighing upwards of 90 lbs. had been grown in this country. He evidently opined correctly, as Mr. A. Simmonds writes, "it is recorded (in the *Gardeners' Magazine*), that in 1821 a Mr. George Davenport, gardener to Mr. H. P. T. Aubrey, at Broomhall, near Oswestry, grew a Pumpkin weighing 136 lbs."

Mr. F. J. Foster.—Both at the Royal Horticultural Society's exhibitions and at Midland shows, Mr. F. J. Foster, gardener to the Earl of Ancaster, Grimsthorpe, Bourne, Lincolnshire, has been a most successful prize-winner with fruits and vegetables. Although Mr. Foster does not pretend to "specialise," he is an extremely capable gardener, and in charge of a very interesting garden. His experience in gardening has been obtained by employment at such famous gardens as those of Petworth Park, Syon House, Hutton Hall, Forde Manor, Culford Hall and Milton Abbey. Before taking charge of the gardens at Grimsthorpe Castle—where he receives every possible encouragement from the Countess of Ancaster—Mr. Foster was gardener to the late Hatfield Harter, Esq., at Cranfield Court, Bedfordshire.

MR. F. J. FOSTER.

Scottish Potato Trade Crisis.—At an urgency meeting of the Directors of the Scottish Chamber of Agriculture, held at Edinburgh, on Wednesday, December 11, Major Sharpe, Earlston, presiding, Mr. J. L. Anderson, Pittormie, Fife, suggested that public attention should be drawn to the extraordinary gravity of the present position of the Potato trade. He suggested a temporary measure to meet the present crisis, without prejudice to the Government's general policy, in the way suggested by Sir Harry Hope, of fixing a reasonable maximum price and keeping out imports so far as Potatos were concerned, without raising the price to consumers. Sir Isaac Connell thought they should strive for what they had already decided on—that there should be a prohibition of the import of Potatos so long as a fixed price was not exceeded, and they had home-grown Potatos to sell. They should not delude themselves into believing that schemes of co-operation and so on formed a solution. The solution was the prevention of free importation of foreign produce. The Chairman said they were tackling a very difficult proposition. His opinion was that either to ask for protection or subsidies, or even prohibition of imports, almost ran them into a political issue, and he doubted if any party in the State would support that without a mandate from the country. After further discussion, it was agreed to circularise every member of Parliament in England and Scotland and arrange, if possible, a conference with the Prime Minister and the leaders of the other parties.

Snowdonia as a National Park.—All those who love the wild beauty and grandeur of Snowdon—the highest mountain in England and Wales—and the surrounding district, will earnestly hope that success may attend the scheme now being placed before the Government Committee which has been appointed to consider and advise upon the establishment of national parks in Great Britain. This scheme has for its object the acquisition of Snowdon and the adjacent mountain groups that extend across Carnarvonshire and into Merioneth—a total of about three-hundred-and-fifty square miles. How much money will be needed to acquire this large mountainous area is not known at present, but negotiations are proceeding in view of an early meeting of the Government Committee and the Council for the Preservation of Rural Wales.

Presentation to Mr. Walter P. Wright.—Following the retirement of Mr. Walter P. Wright from the position of Horticultural Superintendent under the Kent Education Committee, after thirty-six years' service, the Kent Teachers' Association organised in his honour a reception and the presentation of a handsome piece of plate, suitably engraved. Mr. Paul, Chairman of the Association, paid a warm tribute to the recipient, who, he said, had won the esteem of the whole body of Kentish teachers by his unfailing courtesy and kindly sympathy. Mr. E. Salter Davies, M.A., Director of Education in Kent, followed, and expressed eloquently the respect and affection of the administrative staff. The presentation was made by Sir Mark Collet, Bart., Chairman of the Kent Education Committee, who voiced the high appreciation of the Committee of the work done by Mr. Wright in every branch of horticultural work, and particularly in the development of school gardening; he said Mr. Wright carried with him into retirement the respect of the whole community for long, arduous and loyal work, conducted with a high sense of public service.

A Winter Exhibition in Ghent.—The Azalea growers of Ghent, Belgium, are combining to organise a December exhibition of flowering Azaleas, Cyclamens, and other ornamental pot plants, in the vast building of the Bourse. The Burgomaster of the City, and the Comte de Kerchove de Denterghem, have promised their patronage, and large numbers of exhibits are expected, so that the show is likely to attract a good attendance. The exhibition is to be open from December 21 to 25, inclusive; the dates may surprise English readers, but in Belgium Christmas Day is not kept so sacredly as a day for the home as it has been for the last century or so in this country.

The Alpine Garden Society.—The inaugural meeting of the Alpine Garden Society was held at the Royal Horticultural Society's new hall, on December 10. Sir William Lawrence was elected President; Mr. Selwyn Duruz, Le Chalet, Montagu Gardens, Wallington, will be the honorary secretary; Mr. F. H. Fisher will be the assistant secretary for the North of England, and it is hoped to appoint an assistant secretary for Scotland. The annual subscription is 10s. 6d. and should be sent to Dr. Giuseppi, Trevose, Felixstowe; life membership has been fixed at ten guineas, The following have consented to serve on the Committee :—Mr. George Baker, Mr. George Yeld, Dr. Giuseppi, Mr. Renton, Mr. Amos Perry, Capt. Symons-Jeune, Mr. W. E. Th. Ingwersen, Mr. H. Cowley, Miss Victoria Slade, Mr. Fisher, Mr. Clarence Elliott, Viscountess Byng of Vimy, Mr. Maurice Pritchard, Mr. F. C Puddle, Mr. J. R. Pulham, Mr. G. Reuthe and Mr. Edwards. It was decided to hold the first show of this society on May 8 and 9, 1930, and to organise other exhibits throughout the season. The appointment of an Editor is under consideration, and it is hoped to publish pamphlets written by experts on different genera and the like at intervals of not more than two months.

Old Scottish Trees.—In Part I of Vol. XLIII of *The Scottish Forestry Journal*, the Editor appealed for data and facts concerning outstanding Scottish trees. A direct result of this appeal is the publication of a very interesting article in the recently issued Part 2 of the current volume entitled "Some Old Scottish Trees," in which the author, Mr. John T. Smith, has collated considerable data concerning a number of famous Scottish trees, both past and present. Among those still living is the Ash tree behind Craigmyle House, Aberdeenshire, which, according to tradition, was planted by Mary, Queen of Scots, after the Battle of Corrichie. In a garden at Leven, Fife, are a pair of Ash trees, secured as slips from an Ash tree by the grave of Napoleon in St. Helena, in 1842, two years after Napoleon's remains had been removed to France, by a Captain Younger. These trees have grafted each on to the other, and having been trained horizontally along a pergola now extend some thirty feet from the main trunk. At Prestonpans, an ancient Thorn tree marks the spot where Colonel Gardiner, Sir John Cope's commander, fell, in 1745. In Midlothian, on the Dalkeith Road, near Craigmillar Castle, stands Queen Mary's Tree, a Sycamore stated to have been planted by Mary, Queen of Scots, in 1561 ; its hollow trunk has been filled with cement in an effort to preserve it. Alleged to be the oldest specimen of vegetation in Europe, the Fortingal Yew tree, at Kenmore, Loch Tay, Perthshire, is stated to be about 3,000 years old. The original tree decayed, but new growths sprang out from the rotting trunk. At Dunning, Perthshire, an old Thorn tree commemorates the burning of the village by Mar's forces during the retreat from Sherrifmuir in the 1715 rebellion ; the base of the tree is now cased with lead. Another ancient tree which still stands, but does not seem likely to last much longer, is Rob Roy's Tree, a well-known Oak on the Glasgow to Killearn road, near the Glengoyne Distillery. In Guthrie Smith's book on the parish of Strathblane, published in 1886, the author states of this tree, "and the same Oak tree which was growing on the 'march' in 1493 is still growing on, in green and vigorous old age." It was then known as the Meikle Tree. Mr. Smith suggests that the Royal Scottish Arboricultural Society should make a collection of photographs of ancient Scottish trees and publish them, with information concerning them, in book form.

National Bulb Society's "Year Book."—One of the chief aims of the National Bulb Society, which was formed last year, is to encourage the growing of British bulbs, and with a view to furthering this object, Mr. H. W. Abbiss, Horticultural Superintendent for Cornwall, has contributed a brief account of the bulb industry in this country in the first *Year Book* published by the Society ; Cornwall and Lincoln are the chief bulb growing areas in the British Isles : for the production of early blooms Cornish bulbs should be secured, while for bulbs for general planting gardeners should place their orders with Lincolnshire growers. Other short articles appearing in the *Year Book* are "The Daffodil," by Mr. A. F. Calvert ; "Lilies," by Mr. R. W. Wallace ; "Some Wild Species of Tulip," by Mrs. E. Katherine Dykes ; "Bulbs in the Home," by Mr. W. J. Stewart ; and "Some Uncommon Bulbs." by Mr. W. H. Jenkin. A bulb-planting table, showing the best month in which to plant various bulbous subjects, the depth at which to plant and the distance apart, is included, and the *Year Book* also contains the Schedule for the Society's Spring Flower Show, to be held in the new hall of the R.H.S., on April 8 and 9, 1930. The Schedule contains thirteen classes, eight challenge cups being offered for competition. The *Year Book* of the National Bulb Society may be obtained from the Hon. Secretary, 9, Gower Street, Bedford Square, W.C.1, price 1s. to non-members, and at the reduced price of 6d. (post free), to readers of *The Gardeners' Chronicle*.

Retirement of Dr. A. B. Rendle.—It is announced that Dr. A. B. Rendle will retire from the post of Keeper of the Department of Botany in the British Museum, an office he has held since 1906, in January next, and will be succeeded by Mr. J. Ramsbottom, deputy keeper of the Department of Botany since November, 1927.

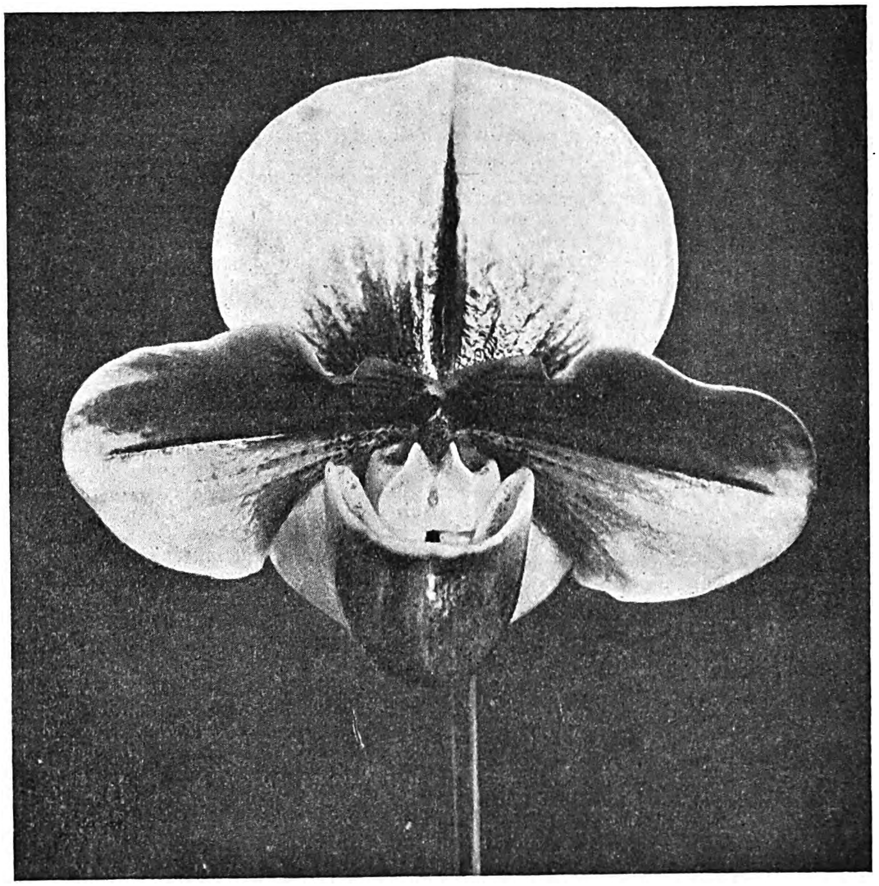

FIG. 221.—CYPRIPEDIUM VESPER VAR. VIRGINIA.

(see p. 473.)

Appointments for the Ensuing Week.—SATURDAY, DECEMBER 28: Leeds Paxton Society's Discussion on the Season's failures.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Vegetation of the Crimea.*—In the first part of Dr. Clarke's travels in various countries of Europe, etc., are several chapters wherein the details of the author's journeys in the Crimea are given. In some of these journeys, too, the doctor was accompanied by Prof. Pallas. The descriptions of Inkermann and of Balaclava (of the harbour of which town an engraving is given), possess great interest at the present moment, while an appendix containing a list of the plants gathered in the Crimea may also be serviceable to a botanist. Scattered throughout the book there are allusions to the vegetation of the country, which are interesting in reference to certain articles that have lately appeared in the *Chronicle* on this subject. In speaking of the "principal spontaneous vegetable productions of the rocks and mountains upon the south-east of the Crimea," he mentions the wild Sage as "growing, in some instances to such a size as to be almost considerable enough to rank as a shrub." The black Date (? what is meant), the Pomegranate, the Olive and the Fig tree, are said to "flourish along the coast as in the south of Italy." Vines are alluded to as covering the porticoes of all the doors in Balaclava, and as growing so rapidly that in two years one Vine yielded two bushels of Grapes. The mountains as well as the plains are mentioned as being "thick set with Oak, Wild Pear, Crab and Cornelian Cherry," while the villages are overshadowed "by an exuberant vegetation of the Walnut, the Mulberry, the Fig, the Olive, the Pomegranate, the Peach, the Apricot, the Plum, the Cherry, and the tall black Poplar." The Crimean Water Melon is said not to attain half "the size in which it is seen at Naples, but the flavour is nearly as fine ; while at Cherson, which is more to the north, it grows as large as in Italy." The flora of the south of the Crimea, judging from the plants enumerated in the above-mentioned appendix, as well as from specimens from Compère and others deposited in the Fielding Herbarium, would appear to resemble to a considerable extent that of the Archipelago, especially in the prevalence of species of Cistus, of Salvia, and of other southern genera ; but it is in the sheltered valleys that the luxuriant vegetation described by Dr. Clarke occurs ; elsewhere, and especially to the north, so different is the aspect of vegetation, that "the narrow tract of cultivated land on the southern coast may be compared to an edging of lace on the lower rim of a large apron." *M. T. M., Botanic Gardens, Oxon.—Gard. Chron.. December* 23, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Zygopetalums.—Specimens of the bulbless kinds of Zygopetalum, such as Z. Lalindei, Z. Klabochorum, Z. gramineum, Z. Roezlii, and others which are often cultivated under various generic names, notably Bollea, Warscewiczella, Pescatorea, Kefersteinia, etc., but are now included in the genus Zygopetalum, are now in active growth, and new roots are being produced from the bases of the partly developed growths. They should be encouraged by carefully removing any sour compost and inserting fresh fibre and Sphagnum-moss in equal parts very carefully among the fleshy roots which, incidentally, are easily damaged and liable to decay if broken or severely bruised. Unless repotting is necessary owing to the plant being overgrown or leggy, it is not advisable to disturb the roots, as they take a considerable time to recover after being repotted, therefore top-dressing or the removal of the compost without disturbing the roots too much is the best treatment. Ample drainage is necessary as these Orchids always require moisture at the roots and should never be allowed to remain dry for any length of time. It is often difficult to find the most suitable position for these subjects. They generally thrive well in a moist and shady corner of the warm house, where the temperature is kept as equable as possible. The plants quickly deteriorate in a hot and dry atmosphere. Thrips and scale insects should be removed by careful sponging with a mild insecticide so soon as detected, as these pests quickly disfigure the tender foliage; spraying during suitable weather should also help to keep them in check.

Robust Species.—The more vigorous species which form pseudo-bulbs, notably Z. crinitum, Z. Perrenoudii, Z. intermedium and the beautiful hybrids Zygocolax Charlesworthii and Z. Wiganianus, thrive in the intermediate house. Many of these are now in full growth and should be given ample supplies of water at the roots each time the compost becomes dry until growth is complete, when a less quantity should suffice to keep the roots fresh and the pseudo-bulbs plump, but prolonged periods of drought should not be allowed. Any necessary repotting may be done when the young growths are in an early stage of development, while those that flower in conjunction with the production of the young growths should be repotted after the flowers have been removed. Use well-drained receptacles and a compost of two parts fibre, one part fibrous loam, one part chopped Sphagnum-moss, and a few dried Oak and Beech leaves well broken up, adding crushed crocks and charcoal to keep it porous. The robust and well-known Zygopetalum Mackayi is now producing flower spikes, and should receive similar cultural treatment as advised for the above, but given a more liberal amount of pot room when repotting. Most of the Zygopetalums require ample supplies of moisture when in active growth, but resent saturation, which quickly induces attacks of the unsightly black spot on the pseudo-bulbs and leaves. Also, moisture should not be allowed to collect in the folded leaves of the young growths or decay may set in. After the pseudo-bulbs are fully developed, the syringe may be used on the plants during favourable weather without any fear of untoward results. Large scale insects often attack the undersides of the leaves, therefore the plants should be examined frequently and the pest removed by sponging so soon as detected. Zygopetalum Gautieri and others with creeping rhizomes are best grown attached to a piece of Tree Fern or to a Teakwood raft, and fixed in a pot, fastening on the compost of fibre and Sphagnum-moss with fine copper wire and extending the raft or block as required.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Spraying Operations.—Preparations should be made in advance for this very important item of orchard management, for it is of the utmost importance that all spraying material should be at hand the moment it is required. This is particularly necessary when one considers the variability of our climate, and the few days during the dormant season when conditions are favourable for spraying. Few things are more annoying than to find that these few opportunities cannot be grasped owing to the lack of material or machinery. A spraying plan should be drawn up and an estimate obtained as to the amount of spraying material required, and the order dispatched to the manufacturer at once. To arrive at such an estimate it may be helpful if I state that a fully furnished bush tree having a spread of ten to twelve feet will take from one-and-a-half to two gallons of diluted spray; those with a spread of twenty feet, or lofty standard trees, may require from three to five gallons of diluted spray to be effective. Every twig and bud should be covered by the spray to secure the best results, for it is here that the eggs of all the moths and of the aphidae are deposited, and not so much on the trunks or main branches. The various forms of tar distillate at five to seven-and-a-half per cent. are most effective in destroying the eggs of most of the aphidae. At this strength it can be applied to the soil of Raspberry stools to destroy the larvae of the Raspberry weevil, and the pupae of the Raspberry beetle, and Black Currants to rid them of aphis as they are the chief "carriers" of big bud mite and of "reversion." Lime-sulphur is, at the present time, the most popular all-round fungicide for winter work. When used at winter-strength, *i.e.*, five per cent., it is most efficacious against scab and mildew on Apples. When employed against Black Currant mite, however, the strength should be a little over eight per cent., or roughly one part in twelve of water. Lime, when used as a cleansing wash, is both economical and efficient, for it cleanses the trees effectually from Lichen and slime, has a corrosive effect on aphis eggs, and will kill the hibernating caterpillars of the codlin moth (Carpocapsa pomenella), which are to be found sheltering under the loose bark of the tree trunks. It is most effective when used as a cover wash, just before the buds burst in spring, against Apple sucker (Psylla mali) which is so destructive to the blossom buds, many of which fail to open properly owing to the ravages of the sucker while in the "louse" stage. This wash should be made from the best Buxton lime shells, 20 lbs. to 28 lbs. to fifteen gallons of water, and put on while hot and through a very coarse nozzle. The lime shells should be placed in a wooden tub, and sprinkled with just enough water to make them fall to powder. If the tub is covered with a sack the operation of slaking will be hastened. Water should then be added to the powder, five gallons at a time to make up to fifteen, stirring briskly the whole time. The wash should then be transferred to the sprayer. Run it through coarse sacking in the process so as to remove any grit which may choke the nozzle, and apply to the trees at once.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Begonias.—Specimens of Begonia Gloire de Lorraine should be removed from the show house so soon as they are past their best and have their growths shortened somewhat with a view to procuring cuttings for next year. Plants that have not been used for grouping in the dwelling-house are to be recommended as most suitable for this purpose. Retain only those plants that have made strong growths at the base. Experience has taught me that success with these Begonias depends largely on the constitution of the plants that are to furnish cuttings. After the plants have had their growths shortened they may be kept slightly drier at the roots, but not to such an extent as to cause flagging, and subjected to a somewhat lower temperature. Any specimens attacked by Begonia mite should be vapourised with sulphur, for it is essential to check this pest if the best results are to be obtained. Late Begonias that are being grown to furnish specimens for decorations during January should receive applications of liquid manure to assist them in the development of their flowers. B. Mrs. Peterson is a very useful late variety. Other winter-flowering Begonias, such as the varieties Optima, Exquisite, Ideal, Mrs. Clibran and others of this type, should be subjected to a slightly lower temperature and kept somewhat drier at the roots when they have passed out of flower, but they should not suffer from entire lack of moisture during the resting period. For the present it is not wise to shorten the growths of these Begonias.

Euphorbia pulcherrima.—As the bracts of the early specimens of Poinsettias reach maturity, fertilisers may be gradually withheld. If watering is carefully attended to and the plants are not subjected to fluctuating temperatures, there is no reason why the bracts should not remain in good condition for several weeks. Later plants should be kept well supplied with weak stimulants until the bracts are well developed. During fogs it may be wise to keep all the ventilators closed.

Tibouchina semidecandra.—This plant, often called Lasiandra macrantha, is a useful subject for flowering at this season of the year, its large, violet blooms being produced over a long season. It is also a suitable plant for covering walls, and when used for this purpose should be planted out in small, prepared borders. If grown in pots for furnishing the conservatory, plants should be secured early in the forthcoming year as cuttings root readily in light, open soil in a close frame with slight bottom-heat. This plant makes long-jointed shoots, therefore to secure a well-furnished plant it is important to stop the growths very frequently during the summer months.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P Ford Manor, Lingfield, Surrey.

The Early Orchard House.—Where the early trees have been placed in position they may now be assisted by mild fermenting material. A night temperature of 45° to 48° should be maintained until they come into flower. When the petals begin to show colour the house should be lightly fumigated on a calm day and well syringed the following morning, to ensure immunity from aphis while the trees are in flower. When this stage is reached a little more fire-heat will be necessary, particularly during the day, as Peaches especially always set best when a free circulation of fresh warm air is maintained to favour the ripening of the pollen. A slight reduction of moisture at this stage is necessary, but unless the weather is wet or foggy, the walls and paths may be damped after gentle heat has been turned on for the day. From this stage onwards the temperature may range at about 60° through the day, and approximately 50° a night, according to the outside atmospheric conditions. The general orchard house should be put in order so soon as cleared of Chrysanthemums. The weather conditions have been too mild for the buds on Peach trees stood in the open and consequently they have become softened, therefore the trees should be housed before severe weather threatens. Pears, Cherries and Plums and the later Peach trees may be left out-of-doors until the end of the year, when they should be housed.

Strawberries.—A few Strawberry plants may now be moved under glass. Fresh air should be admitted freely until the fruits begin to swell, and the house kept moderately warm, although dry. Fire-heat is most injurious, as it necessitates frequent watering and syringing. Once the flowers begin to open the temperature may be raised by a free circulation of hot water through the pipes, and this should also keep the air in motion and prevent condensation of moisture. Large, well-developed flowers may set well enough without the aid of a brush, but at this early season it is well to leave nothing to chance. Careful watering and mild fumigation throughout the early stages should not be neglected. Successional batches of Strawberry plants may be cleansed and brought forward in shallow pits filled with fermenting leaves, while others may be placed in the closed Peach houses and vineries.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Lilium giganteum.—Those who have been privileged to see this giant Lily from the Himalayas, so huge in size and different in aspect from any other Lily, growing in masses under genial conditions, cannot fail to wish to possess a colony of it. It is essentially a Lily of the woodland in the south, loving the shade of large overhanging trees; under the duller skies in the north it is happy on the fringes of bold shrubberies. It is one of those plants that must be planted in groups before its full value can be realised; it certainly is no good planting a single bulb and expecting to see the full grandeur of this noble Lily. Grouped in the woodland or shrubbery amid proper surroundings, the towering stems, which under favourably moist conditions will reach a height of ten to twelve feet, and form a striking and picturesque feature at flowering time. L. giganteum likes a deep, rich, well-drained soil, and the site ought to be deeply trenched, adding a plentiful supply of well-decayed manure, loam and humus as the work proceeds. Water and liquid manure may be afforded during the growing season if long periods of drought prevail; but the latter should not be required if the preparation of the site was thorough in the first instance. The great mistake usually made by those buying bulbs of this Lily for the first time, is that they invariably ask for flowering bulbs. Such a course can only lead to disappointment, and at times absolute failure. Intending planters are well-advised not to plant flowering bulbs, or the result will be dwarf, stunted plants with a few poor flowers on stems but three or four feet high. It is essential that this Lily be established for a few years before flowering if its true character is to be enjoyed. This can only be accomplished by planting bulbs two or three years old from offsets, and such can be bought at a much cheaper rate than asked for larger bulbs. It may appear to some gardeners to be a waste of time to wait two years or more until the flowers are seen, but it is worth waiting for; and if a few small bulbs are secured and planted each year until those first planted have flowered, no further expense need be incurred in buying new bulbs, as each of the old flowering bulbs should produce from three to five small and medium-sized bulbs. These should be planted so early during the autumn as possible, on freshly prepared sites, to carry on the succession for future years. Stock may be increased readily by seeds which germinate freely, but the bulbs take from six to eight years to reach the flowering stage. When planting, allow the tops of the bulbs to protrude through the soil, and cover them during severe weather with Bracken or leaves, otherwise serious loss may be the result if very low temperatures prevail for any length of time.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Asparagus.—This vegetable lends itself freely to forcing, and crowns from three to four years old give the best results. Several methods may be employed for forcing Asparagus so long as sufficient heat can be maintained to produce quick growth. Where a heated pit can be utilised for the purpose, it is easy to obtain good returns in a few weeks, but where frames have to be used, it takes longer to produce the growths. Place the crowns on plenty of leaf-mould and cover them to a depth of six inches. Keep the roots uniformly moist. Another method is to place frames over portions of the Asparagus bed, banking plenty of horse manure well round the frames as fermenting material for the production of warmth.

Mushrooms.—Beds spawned some seven or eight weeks ago should now be commencing to crop, and some of the rougher covering material should be removed to free the buttons. Succession beds should now be spawned and covered with a layer of fine mould from good turf. Maintain a temperature of from 60° to 65°, but guard against excessive heat. Spray the walls and paths of the Mushroom house frequently with tepid water.

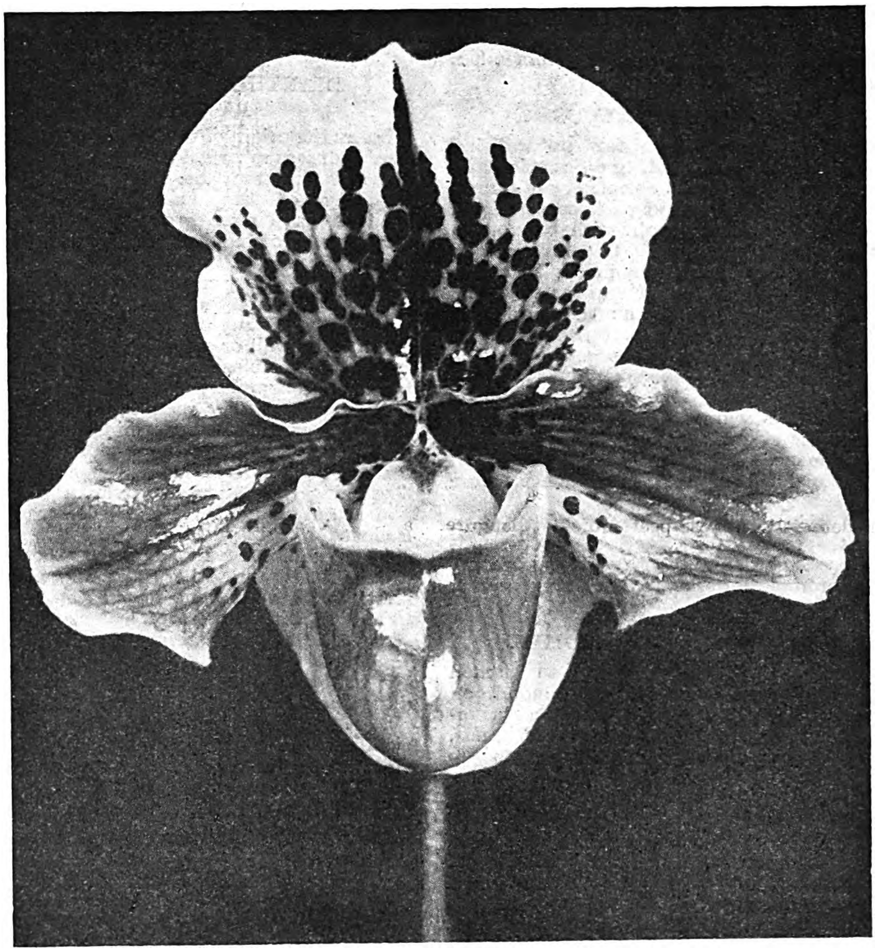

FIG. 222.—CYPRIPEDIUM GERDA.

R.H.S. Award of Merit, December 10. Flowers white and green, spotted with purple.

Shown by Messrs. H. G. Alexander, Ltd.

(see p. 473.)

Cauliflowers.—The Cauliflower plants in frames should receive an abundance of air on all favourable occasions, and any dead or yellow leaves should be removed. Stir the soil between the plants frequently, and grow the plants so hardily as possible as, if allowed to become soft, they are likely to be crippled in very severe weather.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Vines.—Any Grapes still hanging should now be cut and bottled, so that pruning may be finished before the end of the year. It is most important that this should be done while there is still a little sap in the rods to seal the cuts, or bleeding will take place when the sap begins to rise in the spring. The bunches may be stored in any cool, dry, airy room, but it is advisable to inspect the bunches regularly so that decaying berries may be removed so soon as they appear. By this method of storing, the Grapes may be kept in good condition for several months provided the room is ventilated sufficiently to dispel any moisture and a temperature of about 45° is maintained.

Chrysanthemums.—Most of the late-flowering varieties may be propagated so soon as sufficient cuttings can be secured, and varieties not at present producing cutting growths should be cut back, have all the soil shaken from their roots, and the stools placed in boxes, in a compost of light sandy soil, leaf-mould and sand in equal parts passed through a half-inch mesh sieve. If placed in a temperate house and sprinkled occasionally with tepid water, they should soon break into growth. Much has been written lately about rooting Chrysanthemum cuttings in pure sand. No one will dispute the fact that this can be done, but for securing a general stock of garden plants, a light mixture of loam, leaf-mould and sand, with a good surfacing of pure sand, is the best medium, as then there is no need to pot the cuttings directly they are rooted, the young plant having a supply of food in the soil. If rooted in pure sand, they must be transferred to soil at once, which in many cases is not always practicable. The soil, whether in pots or boxes, should be made quite firm so that the cuttings can be inserted just so deeply as to hold them erect. If the soil is damp, sufficient water only should be given to settle them in the boxes and these should then be placed in a temperate frame where they may be kept close for a few weeks, giving a little air for a short time each day and removing moisture from the glass at the same time.

BULB GARDEN.

MUSCARI POLYANTHUM.

I am glad to observe that Mr. Copley (page 424) has contributed a note of appreciation of Muscari polyanthum. I look upon it as one of the best of the Muscaris, although the shade of blue is, perhaps, not quite so bright as that of the popular M. Heavenly Blue. The spikes are larger and the flowers superior in size to those of M. botryoides.

I have a good clump of it in my rock garden and appreciate it highly.

I may be permitted to write a further word in praise of the white variety of M. polyanthum. This is equal in size and in every respect to the blue one, but is a good white, slightly tinted with palest blue at one stage of its flowering. M. polyanthum var. album is the finest of the white forms of the Grape Hyacinth, and a small group I had here last spring was much admired. Both the blue and the white forms are in commerce and can confidently be recommended. *S. Arnott.*

CROCUS OCHROLEUCUS.

This is a good species for naturalising upon the rock garden. It is free-flowering and increases rapidly by small cormlets, an abundance of these being formed each season upon the parent corm. Although perhaps not so showy as many other species, C. ochroleucus is especially welcome as it commences to flower when the greater number of autumn-flowering forms are passing out of bloom; the flowers are not quite white, ivory being a better description, and the throat is stained with orange to a variable degree, almost negligible in some, quite a strong feature in others; very faint grey lines are perceptible on the segments, while the anthers are white, the stigmata yellow. Crocus ochroleucus commences to flower without leaves but, usually, the short leaves are in evidence before the second blossom appears.

This Syrian species I have found to be a most satisfactory plant, and a group of it upon the rock garden is a very satisfying feature when autumnal flowers are becoming scarce. *Ralph E. Arnold.*

MERENDERA BULBOCODIUM.

Merendera Bulbocodium was so named by the famous French botanist Ramond, on account of its resemblance to Colchicum autumnale, which the Spaniards call *Quita Meriendas*, or Takes-away-the-taste, in allusion to its poisonous qualities.

M. Bulbocodium is a small, bulbous plant of the central Pyrenees, and a rare denizen of the French Department Bouches du Rhône. One gathers from books that its only other known habitats are Abyssinia and Afghanistan.

There are three other Merenderas, two of which, M. caucasica and M. Eichleri, are natives of the Caucasus; the other—M. persica—is found in Persia.

The pink or pale mauve, Crocus-like flowers of M. Bulbocodium appear in August and September; the grass-like leaves and the fruits appear after the flowers wither, the latter maturing in the following spring, when the ripened ovary is on a stalk.

The flat part of each of the perianth segments is shortened abruptly into a long, narrow claw which has a small tooth on each side of the contraction point. These teeth are absent on the perianth segments of Colchicums. The three styles of M. Bulbocodium are all free.

Its bulb is covered with a black skin. Quantities of these bulbs grow in the meadows which fringe the mountain streams, or gâves, from Gavarine and Cauterets to Argelès-Gazost. A local botanist told me that in his opinion their original habitat was in the high altitudes, but that, in the course of ages, the mountain torrents when in spate have brought down the Merendera bulbs to lower regions, leaving them in the meadows when their waters have subsided.

If Merenderas would take kindly to our rock gardens they would be a most attractive addition to them at a time when blooms are scarce, more especially if they had their compatriot Paronychia capitata as a carpet.

I brought back hundreds of these bulbs from the meadows in the valley of Lavedan in the autumn of 1927, but I regret to state that not one of those which I kept for myself has survived.

Although I have read that Colchicums and Merenderas require the same soil conditions, I have not found this to be the case in the Pyrenees, where both grow in multitudes. C. autumnale grows there in damp, more or less water-logged, peaty soil away from the streams in the valleys, and on the high mountain plateaux; whereas M. bulbocodium is found, as stated, in the meadows through which the gâves flow, and these fields have a very stony soil, made up of pebbles similar to those which form beaches on the sides of the streams. The soil of the meadows is a rich alluvial one, with perfect drainage owing to the presence of so many stones. *Victoria Slade.*

ALPINE GARDEN.

DIANTHUS CAESIUS VAR. ARVERNENSIS.

What the origin of this rock Pink is I do not know, but it is regarded as a form of D. caesius. However that may be, it is one of the most satisfying of the mat-forming Dianthuses which I have ever grown. It is extremely adaptable, growing in the sun-baked, vertical crevice of a dry wall or well-prepared, flat ledge, with equally happy results. Its very dense and slender leafage of a cool blue-grey shade is always neat and firm at any season, whether it is merely padding the wall or spilling over the edge of its pocket-bed in a closely-knit fold of wind-defying texture and exemplary tidiness. As for flowering, there is not another rock Pink in the garden that can equal this charming plant in the number of its bright, rose-pink flowers and few which can rival it in the extent of its blossoming period. Then D. c. var. arvernensis, as if to round off an already excellent reputation, produces a sufficiency of self-sown seedlings which are almost invariably true to the parent in colour, habit and other particulars. I write "almost" because one may occasionally find a seedling with flowers of a darker or lighter shade, and a pure albino is not uncommon. But the plant never, in my experience, shows any inclination to assume the characteristics of the Cheddar Pink, D. caesius.

D. c. var. arvernensis cannot be a very good friend to the nurseryman, for it is one of the few which never seems to get into one's replacement list. At any rate, I have had it flourishing for nearly twenty years, and it is as hearty and delightful to-day as ever it was. *J.*

SEDUM AMPLEXICAULE AND S. BREVIFOLIUM.

It is during autumn and winter that those delightful little Sedums, S. amplexicaule and S. brevifolium, are most attractive, for it is then that their foliage, which is their trump card, is at its best. The former, as is well-known, goes into its summer sleep so soon as its flowering is over in the later spring, and the dried "stem-clasping" leaves, which then seem as much like hay-seed as anything, do not reappear until called to renewed activity by the autumn rains. Thence onwards, throughout the winter, this Sedum makes attractive little mats of its procumbent stems and wee tufts of linear leaves, which are a cold, bluish-grey, and seldom more than an inch or two in height. Although a native of southern Europe and North Africa, S. amplexicaule is quite hardy. It flowers, as I have stated, before the summer is fully here, sending up an erect, slender stem some four inches high, which terminates in a forked inflorescence bearing comparatively large, golden-yellow blossoms.

S. amplexicaule is a plant for a dry, sunny spot with a gritty, free soil, and the other species mentioned, which makes a good companion plant, can do with even more arid and sun-baked conditions. Indeed, S. brevifolium enjoys nothing better than sharing an almost soil-less rock crevice with the Lichens which usually haunt such places, and once established in such a position it will soon colonise other suitable adjacent chinks by "sowing" them with its small, round leaves which it rolls about in plenty. These leaves are particularly noticeable, as I have suggested, between autumn and spring. During that period their ruddy tint glows to crimson and purple, and their white meal develops a blue-whiteness of extraordinary luminosity. The erect stems which bear these tiny leaves, closely packed in four vertical rows, are seldom much above one inch in height and they produce at their tips in July a few rather small, crystal-white flowers.

S. brevifolium, as above briefly described, has been grown by a good many as S. b. var. Pottsii, and it was that name which my original plant bore when it came here many years ago. But Mr. Potts, whoever he may have been, has been deposed by Dr. Lloyd Praeger and the late Sir Isaac Bayley Balfour, who contend that "var. Pottsii" is indistinguishable from the type. Still the name clings to this little Sedum, but to list it as "S. farinosum" is a good deal wider of the mark. As a matter of fact, S. brevifolium is a species which is signally distinct in an often confusing race. It is one of the gems of its tribe, and quite hardy and amiable in a really dry place. *N. Wales.*

DRACOCEPHALUM GRANDIFLORUM.

One may search a great many catalogues nowadays without finding the dwarf Dracocephalum grandiflorum offered, although in past years it was occasionally to be met with. It had then an unenviable reputation for being difficult to retain in the garden. Slugs are very fond of the plant, and if not checked in time will soon destroy even a strong specimen.

A small coterie of us used to grow this plant, or, rather, *tried* to grow it under the ordinary conditions of the rock garden, but had usually to admit failure. This, naturally, induced us to study the conditions under which others were successful, but even then, when the plant was more plentiful than now, this was not easily done owing to the scarcity of successes. Somewhere about the year 1892, when visiting a small nursery in the precincts of Glasgow, kept by a good grower, the late Mr. Munro, previously of the firm of Messrs. Ferguson and Munro, Edinburgh, I was gratified to see a few very fine plants of it in the open ground. On examination, they were seen to be growing in almost pure ashes, this medium not only helping to deter the slugs, but also affording the thorough drainage required by this Dragon's Head. This was in accordance with Farrer's recipe for the culture of the true D. grandiflorum, of a "very gritty morainish bed, or in the moraine itself, with water flowing below, perhaps, in summer, but as perfect drought as possible in winter." This refers to Dracocephalum grandiflorum of Linnaeus, and the fact that three different plants have been named by botanists D. grandiflorum does not render a search for the true plant any easier.

Thus, Bentham's D. grandiflorum is D. altaiense, of Laxmann and of Willdenow, and D. altaicum, Schangin. But this is an erect plant, six or nine inches high, while the true D. grandiflorum, the subject of this note, is less erect, falling slightly over at first and then rising. The other claimant to the title of D. grandiflorum is D. imberbe. Farrer details the distinctions between these three plants at some length, but it may be stated that the true D. grandiflorum, of Linnaeus, has "the leaves oval-oblong, scalloped or saw-edged, not heart-lobed, but wedge-shaped to the base, and grey with spreading hairs; the flowers are narrower than in the others, less divided, and their whorls not crowded into a head or spike at the top, but perfectly distinct, and with oblong bracts, almost uncut at the edge and ending in a protracted point as fine as a tip of hair." This summary of the points of difference by Farrer's may be of assistance in identifying the true plant. The large flowers are blue and are borne for a long time in succession in summer and early autumn.

While the three plants already discussed are all to be coveted it is well that there should be no doubt regarding their names. I may state that I have not seen the true D. grandiflorum for a considerable time. *S. A.*

TREES AND SHRUBS.

COTONEASTER HUMIFUSA.

Cotoneaster humifusa, Duthie, or Cotoneaster Dammeri var. radicans, of Schneider, is a particularly useful shrub for rockwork, since it hugs the ground or creeps over the stones, following the outlines as if loath to part with them.

This is one of the evergreen trailing species, with prostrate stems which are mealy, with fine hairs while young, and which never become very stout, and bear smooth, oval leaves about an inch long and one-third as wide, curling inwards towards the centre. The flowers are usually borne singly on minute stems. They may be so much as half-an-inch across, although often less than this, and are followed by fruits which are usually described as coral-red in colour. So much for a rather bare account of the plant, which, nevertheless, approximates to the botanical descriptions which have been published.

This species grows well in ordinary garden loam. It does not object to a sunny position, and should be placed so that it can follow the outlines of several medium-sized rocks. Although the stems are comparatively slender, growth is very rapid. Seedlings which have been pinched back form a neat habit, many stems radiating from the centre. This Cotoneaster, although an evergreen, exhibits quite effective autumnal colouring.

It would be interesting to know whether C. humifusa is at all variable from seeds. For example, a plant received under this name from a nursery of unquestionable accuracy of nomenclature, had berries which were deep scarlet in colour, with no suspicion of the coral tone usually attributed to C. humifusa. Incidentally, the specimen made growths which soon became quite stout and comparatively rigid towards their bases. It was a strong, woody plant when received, but well furnished with leaves, and these leaves were beautifully tinted each autumn.

C. humifusa is stated to be a native of central China, and was introduced by Wilson in 1900. The writer has not tested its liking for lime, but Farrer recorded that he found the plant growing "in almost pure limestone silt." He refers to it as C. Dammeri var. radicans, and discovered it in at least one locality on the Chino-Tibetan border, which by the widest stretch of the imagination cannot be called central China. When one also reads of the "brilliant scarlet fruits," one is inclined to ask if this is C. humifusa or not, since, in certain respects, the plant does not appear to coincide with authoritive descriptions of C. humifusa, while in other directions there is agreement. There appears to be a discrepancy somewhere. It may be that C. humifusa is variable, or possibly there are two plants under the same specific name. The writer cannot solve this problem, since he has not all the data at his finger-tips, but, rather than remain in a "fool's paradise," he would admit his difficulties and ask for the facts. *R. C.*

LEUCOTHOË CATESBAEI.

In a Natural Order which has enriched our gardens with numerous treasures such as the large family of Ericaceae, it is not wise to single out plants for special praise, yet Leucothoë Catesbaei is such a splendid all-the-year-round plant that a few words in its favour may be forgiven.

For not only are its Pieris-like flowers very charming, borne as they are on graceful, wand-like growths, but its evergreen foliage strikes an effective note in the open woodland garden the whole year through, and especially at this season of the year when the leaves have taken on their purplish winter tints, somewhat sombre and in keeping with the general tone of winter, but colourful enough to prove an effective relief from the prevailing dull and rather lifeless greens of the Rhododendrons, etc.

At one time included under Andromeda, this species has slender, wand-like, zig-zagged growths, reddish in the young state, which form a bushy clump three or four feet high and as much or more across, and these are furnished with a double row of glossy, leathery leaves, lanceolate in shape and tapering to a long, slender point, with spine-toothed margins; dark glossy green on the upper surface and paler beneath.

The slender, pitcher-shaped, white flowers are produced during May in racemes arising from the axils of the leaves on the upper portions of the stem, but as they droop beneath the foliage their full beauty is not always appreciated; this, however, may be rectified by the aid of forked sticks to lift the growths slightly while in bloom.

There is a form, L. C. var. Rollisonii, which is stated to have smaller and narrower leaves.

L. Catesbaei delights in moist, peaty soil, or it may be grown with success in sandy loam well enriched with leaf-mould. It is quite hardy, flourishes in semi-shade in association with other so-called "American shrubs," and may be increased by division. It was introduced to cultivation in this country so long ago as 1793, and is found naturally in the mountainous regions of the south-eastern United States.

FIG. 223.—HILL JUNGLE, 3,000 ft. alt.; HIBISCUS IN FLOWER.
(see p. 484).

There are several other attractive species in this genus, most important among them being the Californian L. Davisiae, considered by some to be the most attractive member of the family. So far as its flowers are concerned it undoubtedly is, but whether it is such a good all-round plant as L. Catesbaei is open to question.

Of sturdy and compact habit, it forms a neat bush of erect growths furnished with ovate-oblong leaves up to two-and-a-half inches long, and dark, lustrous green, and produces during the latter part of June erect racemes of nodding, white, pitcher-shaped flowers in terminal clusters, and from the axils of the leaves near the ends of the growths. Although not hardy in all districts, it is well worth a sheltered place in the open woodland, for it is a handsome flowering evergreen shrub, its blooms being displayed much more effectively than in L. Catesbaei. It was first discovered by William Lobb, in the Sierra Nevadas, while collecting for the late firm of Messrs. James Veitch and Sons, in 1853, when it was named L. Lobbii. Later, however, it was found by Miss N. J. Davis, whose name it now bears.

L. axillaris differs from L. Catesbaei in having shorter and broader leaves, but otherwise closely resembles that species; it is, however, not so hardy and is stated to be rare in cultivation.

Two deciduous species of Leucothoë, both from the United States, are sometimes included in collections of peat-loving plants, namely, L. racemosa and L. recurva. The former is the most desirable species, and it is an attractive, free-flowering shrub. *M. W.*

HARDY FLOWER BORDER.

LINARIA DALMATICA.

The Dalmatian Toadflax, Linaria dalmatica, is one of the good border plants which are not generally met with in herbaceous borders. This should not be, as it is neither a new nor a rare plant, and is not difficult to obtain from many hardy plant nurseries. It has had a long career in our gardens, having been introduced so long ago as 1731, when it was brought from the Levant.

L. dalmatica is an erect-growing plant with good spikes of flowers which have the characteristic spurs of the genus and are bright yellow in colour. It grows from eighteen to thirty inches in height. The foliage is quite neat and the whole appearance of the plant is distinct.

There is a superior form generally called L. d. var. macedonica, but frequently listed simply as O. macedonica. It grows a little taller, and has rather larger flowers, which are of a finer yellow. But either form is excellent.

L. dalmatica and its variety are perfectly hardy in any good garden soil. Plants may be raised from seeds or secured by taking off the runners which make their appearance about the plant, but which are not usually so rambling as to be troublesome. *S. Arnott.*

CENTAUREA PULCHERRIMA.

I fear Centaurea (or Aethiopappus) pulcherrima (see p. 4.2) suffers on account of its lengthy name, as I find that this is an obstacle to some, especially ladies, who like to be able to tell of the plants in their gardens and are reluctant to tackle one like this. But this plant has merits which constitute a powerful claim for inclusion among one's flowers. I note *North Wales* considers that it might find a place on the rock garden, and where the conditions he suggests can be afforded it should most certainly be given a trial. But it is really a plant for the border, where it may be introduced with advantage.

C. pulcherrima has rather long leaves, silvery beneath, and pinkish flowers of good size, resembling those of some of the better known Centaureas or Cornflowers. This plant thrives in any ordinary garden loam, and is hardy with me. It may be raised from seeds or propagated by division. It is a native of the Caucasus. *Dumfriesshire.*

PYRETHRUMS.

The gardener is often called upon to provide flowers for border displays and table decoration, and in this connection the claims of Pyrethrums should not be overlooked. They fill the dual rôle very well. I have never found that there is any real difficulty in growing them, but undoubtedly the best results are secured when they are grown in a fairly rich, freely-drained soil, and a light situation. If a mulch of manure is spread over the roots in winter, it will protect them during very severe weather, and in springtime will supply useful food.

Although good results can be obtained from seeds, I am sure it is safer and more satisfactory in every way to make a selection of varieties which are available in quantity from nurseries. The present is a suitable time to plant, and the following varieties, in my opinion, rank among the most satisfactory:—Double: Mont Blanc, pure white; Queen Mary, rose, with pink centre; Lord Rosebery, scarlet; and J. N. Twerdy, crimson, tipped with yellow. Single: Queen of Whites, Merry Hampton, crimson; Hamlet, pink; Princess Victoria, carmine; Elsie Gertrude, blush-white; and Fairfax, flesh. *Geo. H. Copley.*

NOTES FROM GLASNEVIN.

November has proved a trying month for plants and gardeners. Nearly four-and-a-half inches of rain made ground work difficult and spasmodic, yet where old shrubs have had to be moved the drought of the past summer was still much in evidence. In spite of the heavy rain there were snaps of fairly severe frost, and not a few plants were caught unprepared. This is not surprising, however, in view of the great number of new species being constantly introduced, and which are as yet comparatively untried and unacclimatised.

So early in the winter some of the newer Rhododendrons have suffered, notably some provisionally labelled "grande series," and that not only in the open, but also in cold frames. A curious condition is shown in R. Griersonianum, on which the shoots terminating in flower buds are as yet untouched, whereas shoots without flower buds are already frosted and wilting; presumably the latter had continued to grow later and were less well ripened. Several visitors learned in Rhododendron matters have assured me R. crassum is hardy, but young plants here are even now ominously brown towards the ends of the shoots. It is unsafe, however, to draw hasty conclusions, as a species may continue to grow late in a mild district and suffer from an early frost, and in a cold district finish its growth earlier and be sufficiently hardened to resist a low temperature. It will take years to decide which of the newer species are definitely unsuitable for the open in any particular garden. One other condition I may mention in connection with Rhododendrons. A young plant of R. neriiflorum was well set with plump flower buds, and while examining the plant, I happened to touch one or two of the buds, and to my dismay they promptly fell off; although green, and to all appearances sound, the centres were brown, rotten and wet. I do not think frost was the cause, but more likely the heavy rains early in October caused a rush of sap to the buds just as they were going to rest for the winter.

A fine bush of R. Fargesii well-furnished with flower buds, some of which are already showing colour, would be a wonderful sight if frost remained absent, but we have the same promise annually, the fulfilment being, perhaps, half-a-dozen flowers sheltered by the upper branches.

Apart from Rhododendrons, there are, fortunately, many other shrubs of great interest and which invite examination as to present and future promise. Viburnum fragrans has never done much at Glasnevin, except make plenty of growth. Our original plant is now a good-sized shrub and is showing numerous flower buds, while other more recently acquired, some of them from Mr. Trotter, of Leith Vale, are equally promising and even in flower. This looks like being a good garden plant and would, I think, be useful for winter flowering in the greenhouse if lifted from nursery quarters in autumn and potted up. Viburnum nervosum (grandiflorum) was never more promising, and given a continuance of mild weather should soon show a pink tinge in the buds. Frost does not kill the buds; they simply wait on the thaw and go on again.

Many writers have commented on the wonderful colour of foliage and fruits during the past autumn. Glasnevin was no exception, but winter effect is reduced to the colour of shoots and stems, such as Dogwoods, Willows, Brambles, etc., and a few berry-bearing shrubs untouched by birds. Among the former the common Cornus alba is scarcely surpassed, but a form known here as the "Westonbirt variety" is of a brighter crimson, although not so free in growth. The various yellow- and orange-barked Willows and the white-stemmed Brambles all help to make the garden interesting.

Acer pennsylvanicum, the Snake-barked Maple, is itself an ornamental species for winter effect, while its variety erythrocladum, with young shoots of almost coral-pink, would be striking were it as free in growth, but a specimen here twenty years old is only a few feet high. Far better is the variety of Acer macrophyllum called aureum, with shoots of the current year coppery-yellow.

The most striking berried shrubs at present are Pyracantha Gibbsii var. yunnanensis, a mass of crimson haws, and P. angustifolia, turning yellow, to become orange after Christmas. Cotoneaster horizontalis is still unsurpassed for its free-fruiting qualities and here and there in the grounds, on the rock garden, and in odd corners unnoticed, perhaps, in summer, the glowing crimson fruits now immediately catch the eye. An unusual effect is produced by Vaccinium glauco-album carrying clusters of glaucous-blue berries, the effect enhanced by a carpet of the fallen fruits on the ground beneath.

The wonderful effect in contour and colour of the various Conifers is too big a subject to attempt here, but looking down the Pine hill from the rock garden a thriving young specimen of Pinus Ayacahuite, bearing a good crop of cones, attracts attention; this species, with much the aspect of P. excelsa, makes a handsome tree and here at least is as hardy as the Bhotan Pine. *J. W. Besant.*

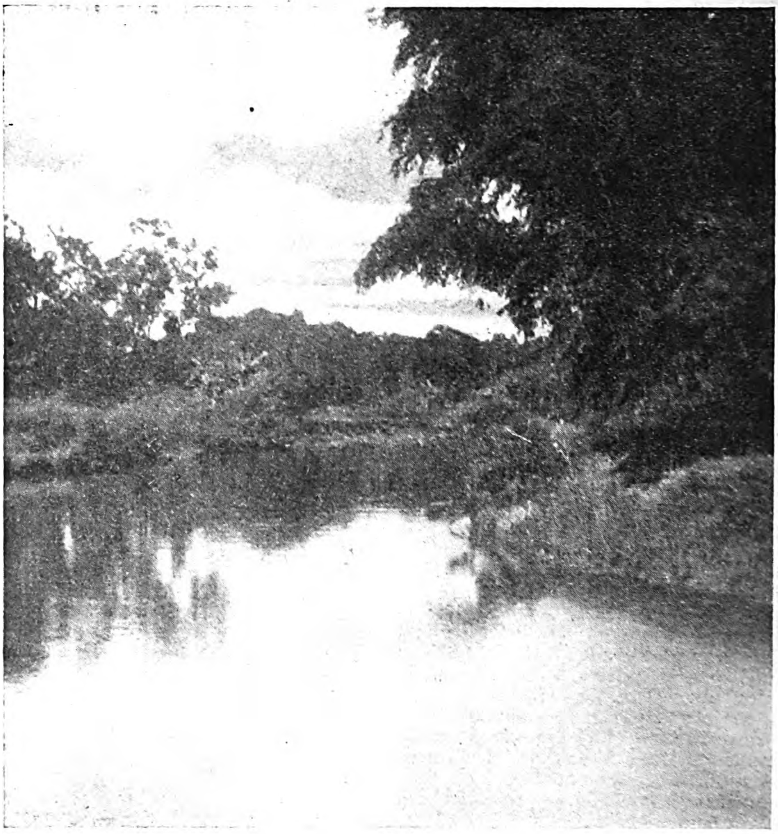

FIG. 224.—A TYPICAL ASSAM RIVER SCENE.

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXXIX.—The Foot-hills.

At this season, that is, in the cold weather, which in northern India is literally the winter, there are very few trees in flower. The Holok (Terminalia myriocarpa) is over, and is even more conspicuously beautiful glowing with the flame of its red fruits than it is in bloom. Bauhinia purpurea var. alba is nearly over. In the forest, a few Myrtaceae (chiefly species of Eugenia) are coming into flower, but these are small shrubs, not to be compared with the big trees. Only Castanopsis indica is putting out its long, fluffy, cream-coloured spikes.

But if there are no trees in flower, so far north as Upper Assam in the winter, neither are there any leafless trees — or very few. The forest is evergreen. It is the dry weather, so far as the rain is concerned, but the atmosphere is always moist, and on the plain it is saturated. This keeps everything green until the hot weather in March and April, when some trees shed their leaves for a short time. The heavy mists which lie over the river on the plain make it feel much colder between sunset and sunrise than the actual temperature would suggest; and I felt warmer at night in the foot-hills, above the one-thousand-feet contour, than I did in Sadiya. The only two leafless trees I saw at this season in the Abor Hills were Lagerstroemia parviflora, easily recognised by its smooth, bleached, columnar trunk, very tall and straight, topped by a small crown of twiggy branches; and Sterculia villosa, just as easily recognised by the few dead leaves which still cling to it. The former is not very common, and always scattered; the latter is common, and sometimes gregarious on the savannahs with Albizzia species.

Although the forest trees do not really begin to flower until after Christmas—and even then it may be remarked they make precious little display in this monstrous ocean of jungle; the herbaceous flora is already going strong. This is most noticeable in secondary growth, where there is much more light than in the jungle; that is, in the neighbourhood of villages and cultivation. Here, out in the open, many of the herbs, particularly species of Labiatae, become small bushes with stout, woody bases. But there are flowers in the jungle, too, the half-shrubby undergrowth of the cool darkness; on the hot, open savannah or parkland of high grass and scattered trees; on the still hotter, stonier chapri, but recently reclaimed from the river; and in the bare stony or sandy river beds themselves. Such flowers as there were belonged almost entirely to the Labiatae, Acanthaceae and Compositae; I shall come to them later.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issue of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; September 7, 16, 28; October 12, 26; November 9, 23, 30; and December 7, 14, 1929.

It was noticeable that there were few Orchids, and still fewer in flower. Being above the mist bath on the plain, Orchids do not thrive in the open savannahs at the base of the hills, and the jungle is generally far too dark for them. A few hundred feet lower down, or a few thousand feet higher up, in the cooler and more open hill forest, we might have found plenty; but we were just in that intermediate belt which is not rich in Orchids. I noticed a few in the jungle, but usually on dead trees, where the light could reach them; and I dare say there were some high up on the biggest living trees. But the most likely place to find them was on big trees scattered in the dry water courses, or along the river bank. As a matter of fact, there were probably as many on the small Jack-fruit trees (Artocarpus integrifolia), which grew in groves around the villages, as anywhere. I collected a Vanda here, said by the Abors to have beautiful flowers, although what the colour was, I could not make out. One curious species, much like Dendrobium triste, was in bloom; the flowers dark chocolate, with a bright yellow lip, borne in a dense spike and smelling strongly of rotten meat!

It is always stated in botanical books that flowers with a foetid smell are attractive to carrion flies, and, by implication, that commoner insects, such as bees and butterflies, which visit sweetly-scented or gaily-coloured flowers, keep aloof. This may be true, so far as it goes, but I believe it is only a half-truth. Certainly I have seen carrion flies, or, at any rate, flies, visiting the nasty-smelling flowers of an Aristolochia; and I confess I cannot recollect ever having seen bees or butterflies visiting any dirty-looking flowers—although it must be remembered that these are not especially common. But the theory that pretty insects only visit pretty flowers, and that only repulsive-looking flies visit stinking flowers is surely based more on a simple association of ideas than on actual observation. No insects are more dirty feeders than butterflies. And why? There is one substance which every creature in the jungle from a butterfly to a buffalo needs, and that is—common salt; although it is anything but 'common' in the jungle!

Anyone who has lived in the tropics must be familiar with the sight of a cloud of butterflies all aflutter on some sand bank by a stream, where cattle have been down to drink. Watching them carefully, one sees that the proboscis has prodded deeply into the wet sand, where it remains, while every ten or fifteen seconds a jet of water is squirted from the anal orifice; and this may go on for many minutes. These insects are taking in salt. Butterflies, however, will seek salt anywhere, such is their need, and it is quite usual to see a host of glittering insects hustling each other on the droppings of some carnivore, whether in the dim jungle, or out in the blazing sunshine; while bees are a perfect pest in the forest, being attracted by human perspiration. In other words, the more aristocratic insects, although they may be definitely attracted by bright colours and pleasant scents, which are almost invariably associated with honey (food), are not necessarily repelled by bad stinks and dirty stains. If butterflies do not trouble to visit odious flowers, it is only because these fail to provide anything worth while—salt, say, or even honey; and what they have on offer is easily accessible to carrion flies, or any other flies with short tongues. Probably the foul smell does suggest salt to these insects—not carrion; and if they do not obtain any salt but do obtain food, at least they are no worse off. The common house fly is the vilest scavenger in Asia, and is generally to be found hanging around carrion flowers; so also is the bluebottle.

To return to the flowers of the forest. Acanthaceae were, perhaps, the most prominent, both for number of species, and in bulk. A species of Strobilanthes was very abundant, forming a regular bush, so much as eight feet high, in the jungle; two other species of Strobilanthes were much rarer. There were also species of Asystasia, Eranthemum, and a Phlogacanthus with purplish-pink flowers. Altogether I noted ten species along the foot of the hills between the Dibang river and the Dihang; had I been able to climb higher I might have found more. Labiatae came next, with eight species—seven in flower. A yellow-flowered Lamium was abundant, and a purple-flowered Teucrium, the latter in deep shade in the jungle. There were a few Compositae, mostly familiar by sight; the only interesting plant was a species of Senecio (?) with tall, stiff, wiry stems, narrow leaves, and umbels of glittering yellow flowers; an extraordinarily lean and sapless plant of the hot, sandy chapri.

Two other shrubs in flower call for notice—the white Buddleia asiatica, a small bush of the open secondary growth (recent); and in the jungle, the long, knotted, red ropes of Thunbergia coccinea, a very common climber in these parts. Other climbers in flower belonged mostly to the Convolvulus family, of which there were two or three species, by far the commonest being Porana paniculata, which capped whole trees with a dome of white blossom.

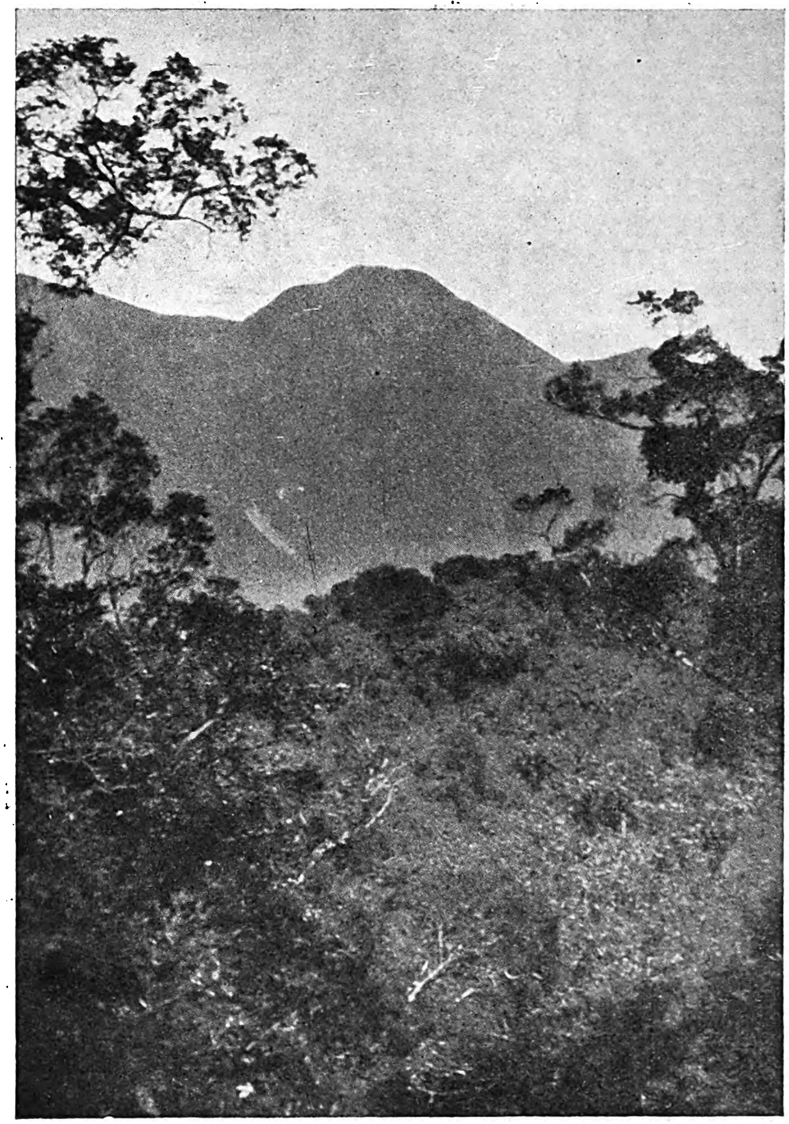

FIG. 225.—HILL JUNGLE, 4,000 ft. alt.; DIBANG GORGE.

It was rather tantalising to march along the slanting shelf just at the foot of the hills, and to look up at them rising tier beyond tier, from 3,000, feet in the foreground to 7,000 and 9,000 feet in the middle-distance, and so through the gaps breached by the rivers, to the snow-glazed high alps in the background; and to feel that above the 7,000-foot contour, so absurdly near, there were probably many new species of plants awaiting discovery. But lack of paths, lack of coolies, lack of any wanderlust and, indeed, lack of energy on my part after our immense exertions in the Mishmi Hills, made it impossible to go there.

I hardly expected to find any new species of flowering plants down below, although in such a country you never can tell. I might, however, find species not previously recorded from Assam. Apart from the fact that practically no trees were in flower, I did not trouble myself much about them; probably they would all have been recorded by forest officers, although almost the only tree that they take any interest in is Holok, so utilitarian has the department become—that, and Cedrela and one or two others. But forest officers are rarely field botanists, and the exceptions, such as the D.F.O. at Sadiya, confine themselves to knowing the woody plants; so that by paying attention to the herbaceous flora, I might be fulfilling a long-felt want, as they say. Someone in Shillong—the hill capital of Assam—was supposed to be writing a flora of the province, surely a monumental work! Even a small collection might add some useful knowledge there, and, of course, our collection from the Mishmi Hills would add many species to any existing lists. Indeed, if 'Assam' includes all the unadministered territory, it must contain by far the richest flora of any province in the Indian Empire, except Burma; and I would hazard a guess that there are hundreds of unknown species lurking in the Abor and Mishmi Hills, although many years may pass before they are discovered.

The journey from Nizamghat on the Dibang to Pasighat on the Dihang was pleasant enough after the toilsome days spent in the Delei valley; although with only ten coolies, I was not travelling in any luxury. *F. Kingdon Ward.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar.* 7818.

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

LILIES IN 1929.

THE year just drawing to a close has been a memorable one for Lilies, and to find anything like a parallel to it one must go back to 1921. In that year, however, the weather of the first quarter was what we regard as normal, whereas in the early months of the present year, the earth was frostbound and with an occasional interval remained so until the beginning of March.

In the home counties there was no sign of a Lily above ground until the first week of April, and that is a good deal later than in any year of the present century. Whether this was due to the frost or the drought which prevailed then, or to a combination of the two, must remain a matter of opinion, and the point is only of interest because in less extraordinary years a late start is usually made up before the June-flowering group has finished its display soon after midsummer.

This year, Lilies seemed to be permanently influenced by their late start, and in spite of the fine weather which prevailed from July onwards, they were about a fortnight later to come into flower all through the season than the average date of the past twenty years. In spite of the hot sun, too, seed capsules were uncommonly slow to mature, and those of L. pomponium, for instance, were not ripe until the third week of September. L. monadelphum, also, did not ripen its seeds until long after the average date.

Apart from the tardy beginning, Lilies had to bear the brunt of as cold a late spring as we can remember, and it is many years since the north-east wind held the country in its grip so persistently or for so long. Time after time, the wind would veer to the south-west for a day, or perhaps two, only to be beaten back by a high pressure system from the Continent. This tussle between the Atlantic and the Continent is typical of our vernal climate, but not for many years has it been waged so bitterly as it was last spring. In the second week of last March, there was a burst of summer which sent the mercury up to a higher point than it had reached during the month for many years; but after two days a return of the north-easterly wind sent it down to an unpleasantly low point. Again, on the eighteenth of April, southerners woke up to find spring knocking at the door and bringing with it soft airs and hot sun. Two days afterwards, they were shivering in a biting north-easterly wind, and Paeonia Cambessedesii was blackened although under the shelter of an overhanging evergreen.

Not until the first week of July was the continental wind finally vanquished, after leaving its mark on the country in the shape of a severe frost on the night of July 1. That did a good deal of harm to the growing stems of Lilies in the south of England, and in many gardens L. regale, especially, was crippled. L. Hansonii is a precocious species, and unless cleverly sheltered from cold winds and frosts of more than 10°F., the young stems regularly pay forfeit. Last April they were badly scorched, but probably because of the dry weather, Botrytis did not follow as it usually does, and ultimately the plants made a welcome recovery. It is not often that anything goes amiss with L. giganteum in a cold spring, but even that suffered last June, and in a peculiar way, as water in the "cup" of the stem-growth froze and killed the flower-bud. An incident of that kind, although not rare in the case of Eremuri, is of interest as illustrating the truth of the saying that gardeners are always learning, for it has not previously come under the writer's notice in thirty years' observation of the genus.

So far as the effect of frost on the bulbs of Lilies is concerned, the frozen ground of last winter taught growers nothing they did not know before. Once again it proved the truth of the observation, so often referred to in these annual notes, that the bulbs of Lilies in general may be frozen hard for weeks on end without suffering any hurt. There may be a limit to the degree of cold the bulbs will support, and those of some species may, perhaps, be more susceptible to intense cold than others; but the point is probably only of academic interest in a country where the coldest winter of a generation has a beneficial rather than a harmful effect on Lily bulbs.

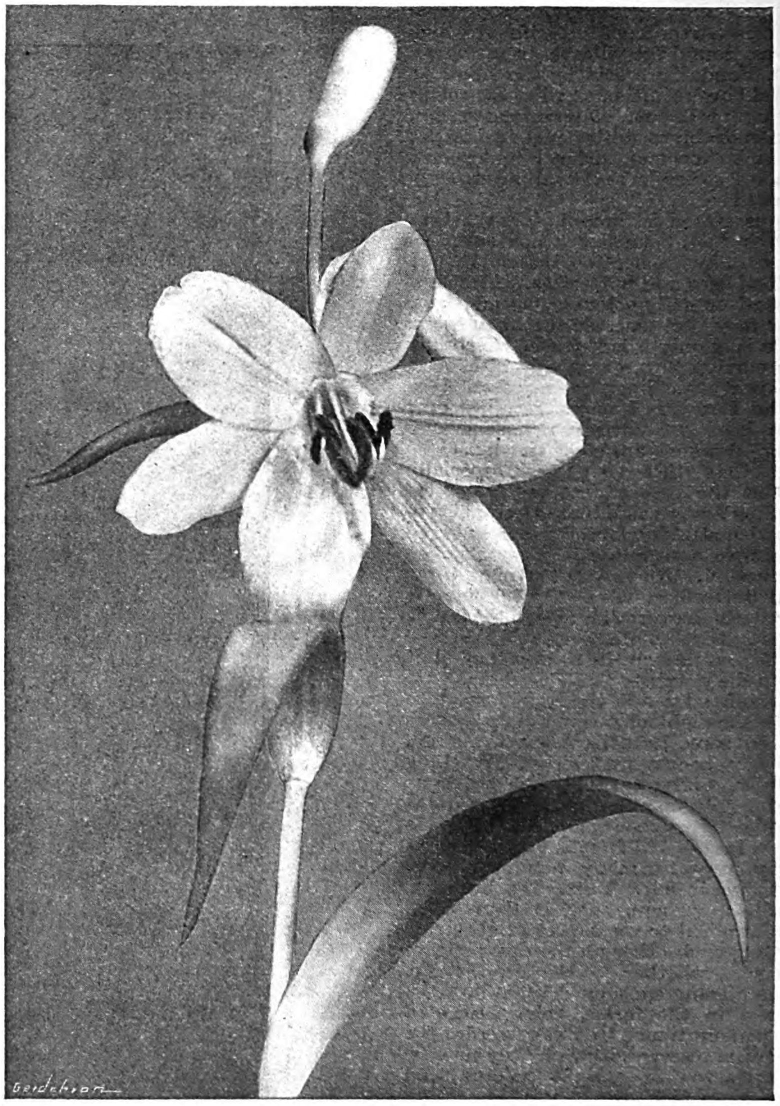

FIG. 226.—LILIUM MACROPHYLLUM, WILSON.
In bloom in Hyde Park, 1929.

The inspiring influence of frost on the germination of Lily seeds, too, has often been noticed, and it was most marked last spring. With seed-pans which were frozen solid in unheated frames until about the middle of March, germination was slow to begin, and in the dry, chilly weather of April, May and June, seedlings were reluctant to make progress; but it seemed as if every fertile seed must have been spurred into life, and when July brought balmy weather, progress was rapid enough to please the most impatient grower.

One effect of the intense cold was to delay the planting of Japanese Lilies, of which the bulbs reach our markets in January and February; and in few places in the south was planting possible until about half-way through March. Luckily, the frost kept the bulbs in good condition, and although, once planted, they were slow to grow, the cold state of the ground and the lack of rain were enough to account for that.

Reviewing the flowering season from early June, when the warm weather began, until the end, the conclusion is reached that the hot summer brought out the good points of Lilies of which the early growth had not been severely damaged by late frosts. At the same time, even during the fine weather, the behaviour of Lilies was far from normal, and sometimes it seemed as if there was some latent influence at work, apart from drought, to throw them out of their stride. A comparison with the summers of 1911 and 1921 is hardly apt, for in neither of those two memorable Lily years were the early months comparable to those of 1929. All three summers were characterised by severe drought, but the heavy rain storm of mid-July, 1929, made a world of difference to those southern gardens which were fortunate enough to lie in its path. The fall, however, was peculiarly patchy, and in some districts it rained heavily on one side of the road and not on the other.

As always happens in a dry summer, those gardeners who had been wise enough to provide irrigation to their Lily beds, reaped their reward. Others, who were content to take their chance, found that by the end of July the characteristic effects of drought were beginning to make themselves felt in familiar ways, and in such places it was interesting to watch the varied effect of a lack of moisture on different species, as the season progressed. As ever, the European species suffered least, because they are naturally able to make a better fight against such conditions than Asiatic species. Most of the latter depend for their welfare mainly on the mass of roots which forms at the foot of the stem, and any check to these has an immediate effect on the growth of the stem and flower buds. This is particularly noticeable in the case of L. auratum and its varieties, as well as L. speciosum and L. tigrinum. It is less noticeable with L. regale, but is by no means negligible in that fine species. Next to sunstroke nothing administers a check to the stem roots of Lilies like drought, and although, in a measure, mulching counteracts the effect of drought for a time in the case of those plants for which there is no water to spare, a drought has only to last long enough to paralyse the functions of their roots. In such a summer as the last, the obvious benefit of shade to most Lilies must have been brought home to gardeners who had not noticed it before. Here, again, the European Lilies are less in need of shade than others, but at such times they all appreciate it and it prolongs the flowering period in a remarkable way. Shading is a difficult problem which every gardener must work out in his own way and from the angle of shelter as well as shade. It is complicated by the fact that in our climate there are many dripping summers when even woodland Lilies need no shade. Then, too, Lilies in the humid climate of the north-western side of the country need far less protection from the sun than those on the southern or eastern sides, and less shelter from spring frosts and rasping winds as well.

Diseases of Lilies have been but little in evidence during the year. It is true that there was a good deal of Botrytis on Lilies in the south in May and June, but a damp atmosphere is an essential element in the life history of this fungus; and so, although the damage done to the leaves by the cold gave the pest the opportunity of systematic impregnation of which it is so quick to avail itself in a year of normal rainfall, the attack never reached serious proportions as it did, for instance, in the wet spring and summer of 1927.

On the other hand, evidence of the frost in the shape of browned leaf-tips was to be seen on Lilies on every side, even when they were in flower in July, and such a tough species as L. Martagon did not escape. The same thing was noticeable in the case of many species of Paeony, of which the earlier leaves were browned, although the flowers were not affected.

In this country, a hot summer and a "sulphureum year" are synonymous terms to Lily enthusiasts, and the Burmese Lily seems much less at the mercy of a dry spell than most other species. Much the same applies to L. Sargentiae, for the climatic conditions which suit one suit the other. It is true that there are gardens in the southern and western areas of Britain where these fine species persist from year to year, but they show their full beauty only in exceptional summers like those of 1911, 1921 and 1929. In an ordinary year, each seems to offer a mute protest against conditions they find too uncongenial, and although, from time to time, they are represented by inexperienced or interested parties as good garden Lilies, it cannot be too often insisted that they are for the few and not for the multitude.

Each may be seen at its best in a cold greenhouse, and then the full beauty of the tropical-looking trumpet of L. sulphureum is apparent; then, too, L. Sargentiae seems almost to rival the classic elegance and port of L. Brownii. Each species is easily propagated by the bulbils which form in such numbers in the leaf-axils, and if these are detached and grown in pans they make serviceable bulbs in three or four years.

There is no particular time for removing the bulbils, but the riper they are the better, and this is determined by their size and colour; when ripe, the bulbils of each species are so flushed with purple as to look almost black.

A simple way of increasing the size of stem bulbils is to pinch off the flower buds and then the energies of the plant are diverted to the nourishment of the bulbils. In such cases they may be as large as Filberts and bunched in clusters of three in the bract leaves, like the Apples one sees on neglected old trees. Those who think about such points will realise that just as the removal of the incipient flower buds makes for larger bulbils, so does the removal of the latter make for finer flowers. In either case the plant is lightened of part of its life's burden. Bulbils should not be sown like seeds, but pressed down up to their necks in the soil of the pan. In mild winters, bulbils of L. Sargentiae are evergreen.

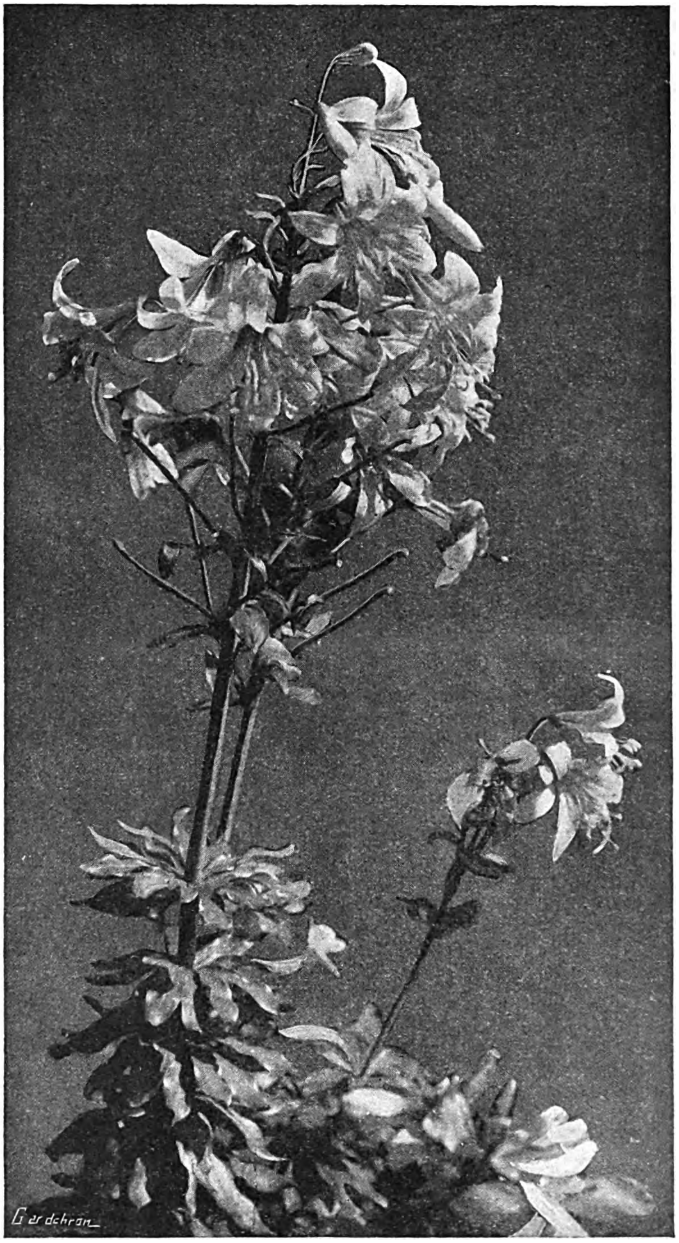

FIG. 227.—LILIUM WASHINGTONIANUM.

An old plant in bloom in Mr. R. Dimsdale's garden at Eastleigh, 1929.

Of Lilies which are comparatively new to cultivation, Ward's No. 6,034 has confirmed the good opinion formed of it by those who have handled it. Whether it can be regarded as a garden Lily like L. regale, L. pardalinum, L. croceum, L. Martagon and L. Henryi, among others, has still to be proved, but meanwhile it cannot fail to find a welcome in places where plants are cultivated for their natural beauty. This Lily is easily propagated, and so should soon find a host of new friends.

During the year, Mr. T. Hay succeeded in flowering L. macrophyllum, Wilson (Fig. 226), from bulbs raised from seeds sent by the Prime Minister of Nepal for use in the Royal parks and gardens. It is never wise to judge a Lily from specimens in the juvenile stage, for such things alter as they grow up, and there is always the possibility that as this particular plant grows up it may prove to be identical with L. hyacinthinum, Wilson. There has been a good deal of confusion about this plant since Don first described it as Fritillaria macrophylla.[*] For the moment, it is sufficient to regard it as an engaging little plant with which those who have a heated or unheated greenhouse may hope to become better acquainted.

In the south of England, the bulbs of all Lilies have ripened well, and that should help them through the battle with the excessive rainfall of the late autumn and early winter. The waterlogged condition of the upper strata of the soil will no doubt prove as deadly as ever to dormant bulbs which have come from afar and are in the ground already or are soon to be planted. Those who are wise enough to pot up such bulbs now and plant them out next year will reap their reward.

---

[*] *Prodr. Fl. Nepal.*, 1824.

An interesting feature of 1929 is the growing interest American gardeners are taking in the cultivation of Lilies. Their interest is fostered by the publication of books dealing with the genus, the issue by dealers of elaborately illustrated catalogues, and by bulletins about the genus and its cultivation prepared by that enthusiastic Lily grower, Mr. David Griffiths, and published by the U.S.A. Department of Agriculture. One such bulletin is that on *A Score of Easily Propagated Lilies*, which was published last year.

So great is the interest in Lilies evinced by American gardeners that stocks of many species and varieties have been depleted, with the inevitable consequence of an increase in the price of bulbs and heavy importations of them from abroad. The American shortage has its repercussions in this country, both in the supply of bulbs of some species and the price.

L. Washingtonianum is not a Lily for everybody, but is certainly one for enthusiasts, as the photograph (Fig. 227) shows. It is of an old plant in Mr. Robert Dimsdale's garden of good things at Eastleach, in Gloucestershire, and was taken last summer.

The characteristic formation of bulblets in the "hair" of the stem-roots of L. regale is well shown in the illustration (Fig. 228). This species is never so prolific a mother as L. longiflorum, but none the less this habit of self-propagation is a useful one if only because it means a gain in time of a year over seminal propagation. *A. Grove.*

PLANTS NEW OR NOTEWORTHY.

PHYCELLA BICOLOR, Herbert.

P. corusca, Van Houtte, in *Flores des Serres*, IV, 419; Amaryllis bicolor, Ruiz et Pavou; Amaryllis cyrtanthoides, Sims, in *Bot. Mag.*, t. 2,399.

There is no doubt that the plant described below belongs to the same species as that well figured by Messrs. Van Houtte. I have also examined the figures in *Bot. Mag.*, and in Ruiz et Pavon. These latter seem to be varieties of the same species. I have not examined the figures in *Bot. Reg.* quoted by Baker (t. 809 and 1943).

Baker has placed Phycella as a sub-genus of Hippeastrum, although, according to him, appendiculate stamens are distinctive of the Pancratiae. Hence it seems a *tour de force* to include Phycella under Hippeastrum. Herbert, who was under the disability of having to work with dried specimens, allowed generic rank to Phycella, which he placed in a group of genera called by him Hippeastriformes. Subsequent botanists have done away with his generic classification and have left the true generic classification of these plants in a state of doubt.

We should remember that the classification of the bulbous Amaryllids had been founded upon the plants of the Old World, and was already to some extent formulated before the Amaryllids of South America were known to European botanists. Hence the inclination of modern botanists has been to push the Andine Amaryllids into any hole or corner in the existing systems of classification. Moreover, the number of living plants available to European botanists is far too limited to enable them to formulate any comprehensive system of nomenclature for such plants as the Phycellas. If Herbert allowed too many species, Baker has probably gone to the opposite extreme.

I cannot find any record of the seeds or fruits of a Phycella, or of any hybrid having been raised between Phycella and another genus.

The plants from which this description was taken were shown in flower by Mr. T. Hay before the Scientific Committee of the R.H.S. on November 19, having been imported from Peru.

DESCRIPTION.

Bulb.—One-and-a-half inch or less in diameter, with a tapered neck. Tunics brittle, dark brown to nearly black.

Leaves.—Five, fifteen to eighteen inches long by half-an-inch wide, rather fleshy, slightly channelled, with rounded back on which the distinct longitudinal veining can be felt; dull on the face, glabrous on the back, the apex rounded. The leaves are flexed and become prostrate at maturity which takes place at the flowering period.

Scape.—Issuing from a central position between the bases of the leaves, erect, not compressed, one-and-a-half foot high over all, bearing an umbel of five scentless flowers opening in succession, about two being expanded on any one day.

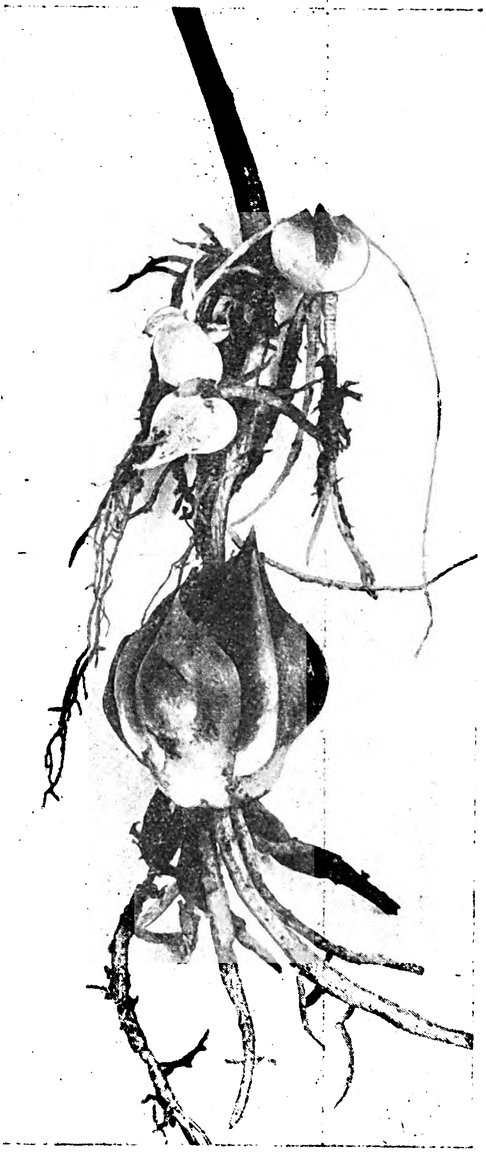

FIG. 228.—LILIUM REGALE.

Showing the habit of forming roots and bulbs on the stem.

Valves.—One inch long, cut to the base, shrivelled at flowering time. Bracteoles one to each pedicel.

Pedicels.—About half-an-inch long at expansion.

Tube.—Bent downwards, about one-eighth-of-an-inch long or rather more.

Flowers.—Bicolored, the lower half yellow, the upper red, semi-patent below, only the tips of the segments being open. Limb one-and-a-half-inch, span three-quarters-of-an-inch. Each flower fades about four days after expansion. In the dark days of winter the yellow parts of the flowers become white.

Segments.—All six about one-and-a-quarter inch long and of equal width, being dilated in the upper half from a width of one-eighth-of-an-inch in the yellow half to three-eighths-of-an-inch in the red.

Stamens.—Contiguous, of unequal lengths, but all slightly exserted, each one accompanied at or just below its point of attachment by one long, slender "tooth" or subsidiary process. Pollen golden.

Style.—Exceeding stamens, ruddy above. Stigma sub-capitate.

Ovaries. — Three-sided, ovules superposed, numerous in the upper part of the placenta.

Fruit and Seeds.—Unknown.

CULTURAL NOTES.

Herbert succeeded in flowering a species of Phycella against an outside wall. I have had but few of this genus under cultivation and can write little about them. Most Chilean and Peruvian Amaryllids are difficult to grow near London, but Habranthus pratensis flourishes in a few parts of England. *A. Worsley, Isleworth.*

PROBLEMS OF PLANT LIFE.*

XV.—THE DESERT FLORA.

WE seem to pass by an easy transition from the last problem touched upon in this series of papers (see page 446) to that which presents itself when we are brought face to face with the plant life of the desert and similar localities. If the problems of the bog are great and many, those of the desert are equally so, although of a totally different character. True, in each case we have an absence of available humus, nitrogen salts and fertilisers, but here drought takes the place of moisture, and as a rule there is an excess of heat, an absence of shade, great exposure to wind and sun, and a constantly shifting bed. Such conditions demand new adaptations, as different from those of the bog plants as are those of the bird which flies from the fish which swims.

The nearest approach which we have to a desert flora in this country is that of our sand dunes, particularly on the sea coast. The text-books, with their learned terminology call the plants which affect dry places xerophytes, and have much to state of xeromorphy and xerophytism. Such terms are better suited to a text-book than to a weekly journal, and will be introduced with the greatest possible economy.

In the case of the desert flora, then, the problems are how to thrive on a minimum of moisture, with excessive heat, little nitrogen, few salts, and an uncertain foothold. Provision has to be made against undue transpiration and special foes and dangers; store chambers may be necessary for the conservation of the water supply, and means of fertilisation and distribution must be provided. Well do I recall my first experience of the desert, and the disappointment I experienced in my endeavours while on my travels to keep specimens of such plants as the Camel's-thorn (Alhagi, or Hedysarum).

Drought may be regarded from different points of view. The dryness may be in the soil or in the air. These may act separately or in partnership, so that we may have a moist soil and a dry wind, or a parched soil with a saturated atmosphere, or atmospheric drought in combination with drought of the soil. Thus, as has been pointed out by many observers, wilting may be produced by a hot, dry wind even upon plants growing in a relatively moist soil. Conversely, growth may be good in a dry soil which is favoured with a moist atmosphere. The true desert usually combines both kinds of drought, there being a minimum of moisture alike in the soil and in the atmosphere.

It follows that a plant which is to withstand the effects of a hot, dry wind in a parched soil must be possessed of special qualities. Some plants meet the need by means of a well-developed root system. This is well seen in the case of our Marram-grass, botanically known as

---

* Previous studies appeared in our issues of April 13 (p. 279), June 15 (p. 446), Vol. LXXXV; July 13 (p. 30), July 20 (p. 50), July 27 (p. 71), August 17 (p. 130), September 7 (p. 187), September 14 (p. 207), September 28 (p. 247), October 5 (p. 268), October 12 (p. 288), November 2 (p. 346), November 23 (p. 406), and December 7 (p. 446).

Ammophila, or the Sand-lover, because its widely creeping root-system binds the grains, and so proves a splendid means of checking sand-storms. Along with this one often finds small, deeply dissected leaves which do not transpire too freely although provided with ample water-conducting tissue. Such are the desert-loving Umbelifers, and such plants as the fragrant Wormwood (Artemisia fragrans). And here it may be remarked that plants of this description are frequently noteworthy on account of their aromatic properties. Gums and resins, oils and essences, fragrant perfumes and ravishing scents, together with vivid dyes and striking pigments, are largely derived therefrom. Valuable as these commercial products have become to man in the course of ages, their existence in regions seldom visited by him suggests that their primary use was not for human beings, but had reference to the plants themselves and to the desert fauna. They were of value in many ways, chiefly we may surmise as preservatives against injury and inducements to birds and animals to render service.

That eccentric but very learned traveller, Richard F. Burton, has many references in his various works to desert plants. We could not "help admiring the perfumed vegetation of the desert," he remarks in one place; describing it as small, tender and *mignonne* as that of Iceland, filling the liberal air with its lavish fragrance. He was a careful collector of such plants, and found the Bedouin full of instructive lore. The chief peculiarities which he noticed were as follows. The foliage is reduced to a minimum. Superfluous moisture is stored up, either in fleshy stems or underground reservoirs against long-continued drought. Gums and resinous matter often encrusts the stems; many plants have glaucous stems or leaves, or are completely covered with a hoary pubescence; not a few are viscous, adhering to the hand like glue, while a large proportion is distinguished by the aromatic odour or by greater or less pungency. Another thing which is noteworthy is the small number of species in comparison with the genera and orders.

A few of the better-known plants of the desert call for mention here. The Old Testament allusions might lead one to suppose that they are in the first place thorny and spinous. The desert is to rejoice and blossom as the Rose, and instead of the Thorn and the Brier, the Myrtle and the Fir tree shall flourish. It is noteworthy that thorns and prickles occur on dry and barren soils, their use being in part defensive. The Camel-thorn is a Legume, and recalls the Rest-harrow, Gorse and other spiny plants. The foliage of such plants and, indeed, their whole appearance, is usually quite different from that of field plants, being marked by a whitish, sea-green, bluish or glaucous appearance. This hue is familiar to us in connection with such plants as the Sea Holly (Eryngium); Sea Buckthorn with the leaves silvery beneath and adorned with a coating of remarkable hairs; Sea Lavender, and other maritime plants found in this and many lands.

Associated with the fragrance of the foliage and the odorous character of the gums and exudations is another interesting feature. The fruits of such shrubs, bushes and trees as occur are often remarkable for their sweetness or pleasing taste and usefulness as articles of food. We may assume that this fact is primarily related to their distribution by birds and animals, but man has not been slow to utilise their good qualities. Palgrave tells us, for example, of a small herbaceous and tufted plant which is found in the desert of northern Arabia and bears the name of Samh. It has juicy stalks and a small, yellow-tinted leaf of an ovate form, the flowers being of a brighter yellow with many stamens and pistils. The fruit is a capsule about the size of a Pea, which contains a mass of minute reddish seeds which are very farinaceous. Growing up spontaneously, the fruits of this plant supply the Bedouins with food which is better than Barley-meal.

Another shrub, which attains a height of two or three feet, is the Mesaa. It yields in summer fruits which closely resemble our Red Currant in size, colour and taste. This is evidently adapted to meet the needs of the desert birds, but man has turned it to account. The Nabak is similar to a small Crab Apple, and although a mere bush in the desert grows elsewhere into a stately tree. The name is variously spelt and translated, as Nebek, Lote, Jujube, Sidr and the like, and the tree is well-known to all travellers in the East because its thorns are said to have been used for making the Saviour's crown. Alhough little can be written from the Englishman's standpoint in favour of the fruit, it is a great favourite with the Arabs of Medinah.

The flora of the desert, then, like that of the bog, shows signs of adaptation. It had to meet a problem, and it did it in a variety of ways, as by developing spines, yielding gums, assuming a pubescent and glaucous appearance, producing fruits suitable for distribution by the birds and animals of the locality, storing up moisture, regulating transpiration and the like. A whole chapter might be written on the latter subject, but it has been so fully treated by others that a repetition of their statements is uncalled for. *Hilderic Friend.*

A FEW UNCOMMON TREES AND SHRUBS.

Whenever I see Pieris taiwanensis at Wakehurst, with its bright red young growths, I am entranced with its beauty; unfortunately Pieris will not grow on the chalk. A like marvel, however, is at hand to console me, in Aesculus neglecta var. erythroblastos, Hort. Späth., the young shoots of which vary from lobster-red to shrimp-pink. This tree will grow to fifty feet, when it must be one of the most beautiful plants in the world. The species comes from North America, and is quite hardy, although a late frost spoils its beauty. All Hornbeams do well here, and I like their elegant, corrugated leaves. Carpinus laxiflora var. macrostachys is, however, something exceptional; the spring growths at the ends of the long, pendulous branches remain bright red throughout the summer. Berberis Nevinii was recently rediscovered by Mr. Menzies, of San Francisco, on the sea-shore near Santa Barbara; it belongs to the Berberis (Mahonia) Fremontii and B. trifoliata class; the elegant, small leaves are glaucous and thickly set on the reddish stems; the flowers are stated to be bright yellow and rather large and the fruits red. Like most Californian plants, B. Nevinii is quite hardy, even in exposed situations, so long as the drainage is good; alongside B. trifoliata it withstood 30° of frost last winter in a wind-swept spot.

Drainage is indubitably the secret of success, whether for Calochortus or for Gilia capitata, or for shrubs like Carpenteria or Fremontia. Fremontia mexicana is generally regarded as a sub-species of F. californica, but their behaviour is very different. Home-saved seeds of the Mexican plant germinate in a few weeks, while similar seeds of the Californian plant take months. The former flowers freely at eighteen months from sowing, the latter takes at least four years. Nor can I keep F. mexicana out-of-doors anywhere. Another Californian plant which will not survive here in the open is Dendromecon rigidum. It flowers freely and in August begins to grow at an amazing rate, until its career is checked by the first hard frost, which kills it. It may be kept alive during mild winters under a shelter or on a wall. In California it doubtless makes its growth earlier and the wood is ripe, the plant dormant and the soil dry when the cold weather comes. Singularly enough, that curious plant, Fallugia paradoxa, with its white, Rubus-like flowers and silky seed-heads, was killed by the drought this year, although it comes from sun-baked Arizona. Many years growing in England must have given it a taste for rain!

Daphne retusa is a great favourite of mine; here, it makes a compact little bush two feet six inches to three feet high. The flowers are as large and as fragrant as those of D. odora, and the plant is prodigal of its scarlet fruits. It may be raised from seeds—I have found self-sown plants—or from cuttings, or may be worked on the roots of D. Mezereum. A very difficult plant to establish is Daphne Genkwa, but the long wands of lilac flowers in May are worth a struggle. I have two good plants remaining from five imported from Japan in 1927. They both flowered freely in 1928 and again, in spite of the winter, in 1929. It is clearly not the cold that kills this Daphne. We grow it right in the open in fairly good natural loam, near the wood and the river; it gets little sun until the late afternoon. Magnolia macrophylla is a deciduous tree with very large leaves up to three feet long and immense flowers some fifteen inches across. It is rare in its native country, South Carolina, and is difficult to layer; it might be worked on M. hypoleuca. Mr. Lionel de Rothschild has some fine young trees at Exbury, and there is, or was, a big tree at Claremont. M. macrophylla is quite hardy, but a slow grower; my plant is thirty years old and about twenty-four feet high. Lady Moore sent me from Ireland a few days ago two pods of Magnolia Campbellii from a tree Sir Frederick Moore knew in 1880, and which has fruited for the first time.

Unfortunately, the fragrant Buddleia asiatica is not hardy, but we have a very good substitute in B. auriculata, which is sweetly-scented and flowers from October to January. Buddleia caryopteridifolia is an interesting Chinese plant that forms its flower buds in the autumn and produces its rather large pink flowers in April.

Salix irrorata has the whitest stems of any Willow and its catkins have warm, brown bracts and golden anthers. A very old garden plant rarely seen nowadays is the Ring Willow, Salix babylonica var. annularis, in which the leaves are curled like a steel-spring; it forms a most comely small tree. Sassafras officinale, although introduced from North America nearly three hundred years ago, is little known in this country. It is a very handsome tree, with large, lobed leaves; the tree at Claremont is sixty feet high. Piptanthus nepalensis is an old favourite, but P. tomentosus, from China, is a more elegant plant, with foliage as silvery as the Cape Leucadendron. It is quite hardy in the open and sets seeds freely.

Danae racemosa (Laurus), the Alexandrian Laurel, is better known in the florist's shop than in English gardens. Yet, in a stiff soil, in a moist and shady position, it will make growths four feet high, which remain bright green throughout the winter and last a long while when cut. The orange berries (not red as stated by Bean) are produced at the end of the spikes after a hot summer. Butcher's Broom, Ruscus aculeatus, is quite a different kind of plant, in which the flowers, and subsequently the fruits, are borne in the middle of the leaf-like cladode. Recently a form has been put into commerce in which both sexes are found on the same plant. This berries freely and is known as B. a. var. hermaphroditus, Hort.

To conclude these notes, may I suggest that we often coddle our plants too much. Most shrubs dislike damp, stagnant situations, and when full of sap, fall easy victims to the frost. Good drainage is more important than good soil; wind helps to ripen the wood and the so-called shelter-belts—I am not speaking of Rhododendrons—are often actually harmful. *William Lawrence, Burford.*

NOTICE OF BOOK.

The World's Grasses.*

The author states that his first-hand knowledge of Grasses was acquired in Great Britain and South Africa, the latter having representatives of the most important genera in the world. He admits that botanical science has not been able to throw much light on the origin of the family. Such fossil Grasses as have been found in Cretaceous and Eocene times are closely similar to the Reed Grasses, Arundo and Phragmites, and might be identical. They are now regarded as having been derived from primitive Liliifloral forms, such as the modern Rushes (Juncaceae). Although allied to the Sedges, they are distinct and form an isolated family, although intricate among themselves. The most primitive Grasses are the Bamboos, and the most advanced are the groups represented by Maize and Andropogon. Bamboos have generally six stamens, though some have only two or one, and while this means an advance, it is not so in general efficiency. The genus Ochlandra is abnormal in having six to one-hundred-and-twenty stamens and eight or more lodicules (perianth parts). Some primitive Bamboos have three styles, and with the six stamens point rather strongly to a Liliaceous floral diagram. In the simplicity of their floral envelopes, the bracts and spikelets of Grasses are the most useful for classification.

---

* *The World's Grasses, their Differentiation, Distribution, Economics and Ecology*, by J. W. Bews, M.A., D.Sc., F.L.S., Professor of Botany in the Natal University College, Pietermaritzburg. With illustrations. Longmans, Green and Co., London, New York, Toronto. 1929. Price 21s. net.

After discussing the general differentiation of the Grasses, the author proceeds in the third chapter with a key to the tribes and genera. The family is Poaceae or Gramineae, in which he gives two sub-families, namely, Pooideae and Panicoideae. These he divides into fifteen tribes, commencing with Bambuseae as the most primitive, the fruit being a nut, berry or caryopsis, the last form being the highest development. A key to the genera is next given under their respective tribes.

Three chapters are devoted to the distribution, ecology and economics of the genera. It is interesting to note that the common Reed Grass (Phragmites vulgaris of Crepin, or P. communis of Trinius) extends all over the world in marshes, on river banks, etc., but that is general in the case of aquatics. The Meadow Grasses (Poa) in the form of different species extend over all the continents of the world, including Australia, New Zealand, and smaller islands. The most important is Poa pratensis, which occupies meadows in all parts of Europe and Asia, while it is, economically, the most important in North America, to which it has been introduced. In a wild state, P. trivialis and P. nemoralis, have a similar distribution. Crossing experiments have shown that Avena sativa and A. s. var. orientalis have been derived from A. fatua, and the Annual Rye (Sicale cereale) from the perennial S. montanum. The Wild Emmer (Triticum dicoccoides) has given rise to eleven races, of which the common Wheat (T. vulgare) is one—a vast collection of mutants and hybrids. It is not surprising that De Candolle in his *Origin of Cultivated Plants*, was unable to give a wild habitat for the cultivated cereals. The Sugar Cane is probably a native of India. Euchlaena mexicana hybridises with the Maize (Zea Mays) of which there are six sub-species, or species according to other botanists. Some of the forms may really be hybrids, for Maize is believed to have originated in Mexico. It is now cultivated in all the warmer parts of the world as human food, and in temperate regions as fodder for stock.

The author gives a statistical summary of 483 genera and 5,871 species, although in another part of the work he reduces the number of species to 5,750. At the lowest computation of Bentham and Hooker there were only 298 genera and 3,055 species, but these authors admitted that other botanists greatly augmented the number in some genera. For instance, they allowed only eighty distinct species of Poa, while the present author admits 200. Of course, some new species have been described since the *Genera Plantarum* was published.

Two chapters are devoted to "The General Ecology of the World's Grasses and Grasslands," and these will prove the most interesting to students and general readers, the previous chapters being of more special use to botanists. Here the evolutionary aspect of the subject is kept in view. The Grasses of the moist tropical and sub-tropical areas of the globe are the oldest and most primitive, because the conditions have been, practically, uniform over a great period of geological time. Changes were introduced as Grasses colonised deciduous woods and others moved into drier regions and became more sclerophyllous. The author traces a migration of sclerophyllous plants from the temperate regions of South Africa, higher and higher upon the mountain ranges as the tropics were approached, until some of their members reached the mountains of central Africa and Abyssinia, thus connecting with the Mediterranean region. This sclerophyllous vegetation, the author states, has chief claims to rank as the oldest of the temperate floras, and includes species of Festuca. The grasslands of the world are old, and derivative from the primitive hygrophyllous ones by long descent. The annuals and ruderal Grasses are very recent, being a response to regions with a wet winter and dry summer. Agrostology, he states, is one of the most important branches of botany, since the Grasses supply most of the food of man, directly or indirectly, as well as the food of herbivora directly and the carnivora indirectly.

The book contains many excellent line drawings of Grasses, and some of sections and diagrams. Paper and type are excellent, and the same may be written of the editing. The principal mistake noticed was Cynosurus aristatus for Crested Dog's Tail Grass, which seems to have been mentioned only from the Montpelier Botanic Garden, as a plant without habitat. In both cases, probably, it was only a *lapsus memoriae*. It should have been C. cristatus. The book contains an extensive bibliography and a good index.

THE GENUS PRIMULA.

(*Continued from p.* 470.)

TONGOLENSIS (Franch.). Tongolo P.

(Petiolaris-Tongolensis).

A little-known dwarf species with a rosette of nearly smooth, thick, oval leaves, two to five inches long, blunt at the tip, rotund or truncate at the base, borne on stalks longer than the blade; margins edged with blunt, rounded teeth. Flower stem slender, two to five inches tall, bearing a solitary blossom the colour of which has not been recorded. Corolla about one inch long, with narrow, shortly bilobed segments; tube narrow, longer than the calyx.

This species is apparently confined to the neighbourhood of Tongolo, in western Szechuan, western China, at a considerable elevation above sea-level.

Culture: As for P. soldanelloides.

TOSAENSIS (Yatabe). Tosaen P.

(Reinii).

A pretty, somewhat dwarf, perennial species with a sparse tuft of membranous leaves, with very broadly oval or nearly circular blades one-and-a-half inch to two-and-a-half inches across, heart-shaped at the base, borne on rounded stalks one inch to three inches long, densely covered with long hairs; margins cut into small, somewhat blunt, toothed lobes; both surfaces covered with long hairs and deeply veined. Flower stalk erect, slender, very hairy, three to five inches tall, bearing an umbel of three to nine somewhat drooping, magenta-pink flowers with yellow throats. Corolla three-quarters- to one-and-a-quarter inch across, divided into five widely separated, rounded lobes bifid at the tip; tube cylindrical, about half-an-inch long. Introduced in 1914.

Grows in damp, somewhat shady places on hills in the Province of Tosa, in Nippon, also in Sikoku, Japan.

Culture: As for P. Reinii.

TRAILLII (Watt). Traill's P.

(Obtusifolia).

A very handsome, robust, deciduous perennial species with a tuft of thin leaves seven to nine inches long, with elliptic, oblong or egg-shaped blades rounded at the tip, gradually tapering to a thick stalk, dilated and sheathing the rootstock at the base, which is clothed with mealy scales when at rest; margins of leaf more or less toothed; underside densely coated with white meal. Flower stem stout, coated with white meal, fifteen to twenty inches tall, bearing two or three superposed umbels of pale blue blossoms on long stalks. Corolla about three-quarters-of-an-inch across, concave, divided into five egg-shaped, entire lobes; tube cylindrical, membranous, about three-quarters-of-an-inch long, with a ten-lobed ring in the mouth. Figured in *The Gardeners' Chronicle*, 1897, vol. xxii, p. 263, fig. 80. Not in cultivation.

Grows in rather dry situations in the dense shade of rocks in rich soil, near the Kangra Kulu and Sharran glaciers, in the north-western Himalayas, at about 16,000 feet above sea-level.

Culture: Rich loam and Oak or Beech leaf-soil, in a well-drained, shady spot, is suggested.

TRILOBA (Balf. f.). Three-lobed P.

(Dryadifolia).

A very beautiful, minute species, hardly three-quarters-of-an-inch tall, with dense rosettes of tiny leaves forming cushions of foliage two or three inches across. The oval, blunt, somewhat fleshy leaf-blades are divided to the middle into three lobes and taper at the base to a short, broad, strap-shaped stalk, in all about half-an-inch long; both surfaces pale green and clothed with minute, meal-producing, glandular hairs, which form a fringe on the margins. Flower stem about one-eighth-of-an-inch long, glandular, downy, bearing a bright rose, yellow-eyed blossom immersed in the foliage. Corolla about half-an-inch long, with blunt, egg-shaped, deeply bifid segments; tube broad, with a dense tuft of snow-white hairs in the throat. Flowers in August.

Grows in stony, alpine pastures near Tsarong, on the Sondre-shan, in south-eastern Tibet.

Culture: Peat, friable loam and limestone chips, in an open spot well supplied with underground moisture in summer, with protection from damp in winter, should prove congenial to it.

TYROLENSIS (Schott.). Tyrol P.

(Auricula-Rhopsidium).

A very beautiful little European perennial species with a stout rootstock which elongates with age and is clothed with the dried remains of previous season's foliage. The leaves are produced in tufts and have almost circular or very broadly oval blades a quarter- to one-and-a-quarter inch long, narrowing abruptly to a distinct stalk; margins minutely and irregularly toothed; both surfaces bright green, covered with many minute, colourless, viscid glands. Flower stem slender, three-quarters- to one-and-a-half inch tall, covered with viscid, glandular spots, and bearing at its apex one or two bright, soft pink, white-eyed blossoms. Corolla over three-quarters-of-an-inch across, with heart-shaped, cleft lobes. Flowers in June and July. Illustrated in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913.

Grows in cool, damp crevices and on the ledges of limestone rocks and cliffs, usually with northern exposures, in the Dolomites of southern Tyrol.

Culture: It should be planted in peat and limestone chips, in a cool but well-drained spot in half-shade; it succeeds in a limestone moraine or in pots in a cool house.

TZETSOUENSIS (Petitm.). Tzetsouen P.

(Rotundifolia).

A smooth, non-mealy, perennial species with a tuft of distinctly stalked leaves with lance-shaped, very pointed blades, three-quarters- to one-and-a-quarter inch long, heart-shaped at the base, borne on narrow stalks three or four inches in length; margins furnished with sharp, saw-like teeth. Flower stem six to eight inches tall, smooth, bearing an umbel of about three yellow blossoms, on stalks about three-eighths-of-an-inch long. Corolla nearly flat, about three-quarters-of-an-inch across, with narrowly oval, entire lobes; tube cylindrical, about three-quarters-of-an-inch long, twice as long as the calyx.

This species is found at Tzetsoue, near Bathang, in eastern Tibet.

Culture: As for P. rotundifolia.

ULOPHYLLA (Hand.-Mazz.). Oblong-leaved P.
(Bullatae).

A dwarf, shrubby species closely allied to P. bracteata, with a slender, unbranched rootstock which produces a rosette of oblong, blunt leaves one inch to four inches long, more or less rounded at the tip, very much undulated, gradually narrowed to a winged stalk which is dilated at the base and shorter, rarely longer, than the blade ; margins more or less edged with coarse, blunt, regular teeth and fringed with fine, glandular hairs ; upper surface sparsely, and underside densely covered with short, glandular hairs. Flower stems one to three in number, slender, shorter than the foliage, bearing many-flowered umbels of yellow blossoms on stalks a quarter- to three-quarters-of-an-inch long. Corolla over five-eighths-of-an-inch across, glandular, downy externally, with broadly egg-shaped, shallowly-notched lobes ; tube cylindrical, slightly longer than the calyx. Flowers in June. Not in cultivation.

Grows on the mountains of Tashwaschan, near Beyendjing, in Yunnan, western China, at about 8,000 feet above sea-level.

Culture : As for P. Forrestii.

UMBRATILIS (Balf. f.). Shade P.
(Soldanelloidae).

A dwarf, sparsely foliaged perennial species with a rosette of deep green, rugose leaves, about three-and-a-half inches long, with oblong or nearly elliptic blades, blunt or rounded at the tip, narrowed at the base into a wedge-shaped, narrowly-winged stalk equalling or longer than the blade in length ; margins furnished with short, pointed or rounded teeth or small lobes ; both surfaces covered with glandular hairs. Flower stem three or four inches tall, slender, deep green, glandular hairy, bearing a head of five or six deflexed, pale purple blossoms, which are bronze-coloured in the bud. Corolla about five-eighths-of-an-inch long, funnel-shaped, with meal-producing, glandular hairs in the throat. Flowers in September.

Grows in damp, shady places in rocky soil in Kurmathang Pumthang, in Bhutan, eastern Himalayas.

Culture : As for P. metria.

UMBRELLA (Forrest). Umbrella P.
(Farinosae).

A very delightful little species with the whole of its foliage, stems and calyces more or less coated with golden-yellow meal. The oblong leaves, in rosettes, are about one-and-a-half inch in length and taper to a wedge-shaped stalk ; the margins below the middle are entire, while above the middle they are recurved and furnished with sharp, saw-like teeth terminating in horny points. Flower stem two to four inches tall, bearing an umbel of six to eight lilac or soft, deep rose-pink blossoms, on stalks about four inches long, radiating from the top of the flower stem like the ribs of an umbrella. Corolla about three-quarters-of-an-inch across, with broadly egg-shaped lobes ; tube about twice as long as the calyx, pale, with lilac veins, more or less sprinkled with white meal both inside and out. Flowers in July. Illustrated in *Jour. Roy. Hort. Soc.*, Vol. XXXIX, 1913. Introduced in 1908.

Grows in stony alpine pastures on the Tali-Range, in Yunnan, western China, also on the shady ledges of cliffs and on humus-covered boulders on the mountains of the Chunchuan-Mekong divide, at 10,000 feet aboove sea-level.

Culture : Calcareous loam and peat, in an open, well-drained spot abundantly supplied with underground moisture when in growth, should suit it ; it increases very slowly.

UNIFLORA (Klatt.). One-flowered P.
(Soldanelloidae).

This exquisite little species produces a sparse tuft of broadly oval, rounded or oval-lance-shaped, pointed leaves about half-an-inch long and a quarter-of-an-inch across, borne on stalks about as long as the blade ; margins deeply pinnatifidly toothed, the teeth being coarse and blunt ; both surfaces more or less smooth and quite devoid of meal. Flower stem two to five inches tall, very slender, bearing one, or very rarely two, stalkless, nodding blossoms three-quarters to one inch across. Corolla pale lilac or pale violet, broadly funnel-shaped or nearly flat, divided into five or six egg-shaped, usually shallow and coarsely-toothed lobes ; tube about one-and-a-quarter inch long, funnel-shaped. Introduced in 1911. *Gard. Chron.*, 1912, Vol. LI, p. 407, Fig. 194.

Grows in damp, rocky soil in the Kankola Pass, in the Sikkim Himalayas, at 13,000 to 15,000 feet above sea-level.

Culture : Light, fibrous loam and peat in a damp, cool spot seem to suit it, but it is best grown in a cold frame and treated as a biennial. *A. W. Darnell.*

(*To be continued*).

INDOOR PLANTS.

CEPHALOTUS FOLLICULARIS.

THE New Holland Pitcher Plant, as Cephalotus follicularis is commonly termed, is a compact, small-growing, warm greenhouse plant that only attains a height of a few inches, but is one of the most singular plants in cultivation. Unlike the Nepenthes, the extremities of whose leaves form pitchers, Cephalotus produces pitchers from its main stem independent of the leaves. These pitchers are borne on stalks from two to three inches long, according to the strength of the plant.

When growing freely, C. follicularis produces suckers abundantly and may be propagated by removing these. They should be detached from the stem in spring, and placed singly in thumb pots. The material in which this subject grows best is fibrous peat and live, clean Sphagnum-moss chopped fine, in about equal parts, with a good sprinkling of powdered charcoal and sand. Press the compost firmly in the pots around the base of the suckers and afford a little water, after which stand them in a propagating bell-glass in a moderate stove temperature, shading them from sunshine. In about two months the suckers should be rooting freely and making leaves, when a little air should be admitted daily by raising the bell-glasses a little at one side. Keep them well supplied with moisture and grow them on for the first season in a temperature of from 50° to 55° by night. By the following spring the plants will require a shift into larger pots, using for this purpose a compost similar to that advised above. As the plants gain strength and increase in size the bell-glasses may be dispensed with altogether, for without the aid of these the pitchers are usually more richly coloured.

Care should be taken in the cultivation of this subject to avoid cold draughts by careful ventilation, and if all goes well the plants will go on increasing in size for several years, producing offshoots freely, a number of which may be taken off and treated as advised above. Greenfly is very partial to this plant and should be kept under control by fumigating with an approved fumigant. *J. N. McGoogan, Wisley.*

EVODIA ELEGANS.

THIS graceful and very useful foliage plant is not unlike Aralia elegantissima in form and habit ; the leaves are coloured a uniform shade of fresh, clear green ; the form is compact, the plant well-furnished and of irregular pyramidal habit. Each leaf consists of three long, narrow, undulated and crenate lobes, not unlike the leaves of several Codiaeums, and a well-grown example should be furnished with them from the rim of the pot to the apex of the stem.

This desirable subject is a native of New Guinea and so enjoys considerable warmth ; it thrives in light, fibrous loam mixed with a small portion of good leaf-soil and some sharp sand, and is not difficult to propagate if half-ripened shoots are secured and inserted in sand, over bottom heat. An older species, scarcely so attractive as E. elegans, is E. triphylla, introduced from the East Indies, in 1821. *R. E. A.*

HOME CORRESPONDENCE.

The Need of Education for Gardeners.—I have read with interest the letters which have appeared recently in your columns upon this subject, but note with regret certain mis-statements which appeared on page 430, from your correspondent, Mr. Bain. This writer states that the instruction given at the various horticultural colleges is mostly inadequate. May I point out that two of the three successful candidates in the general section of the N.D.H. Final Examination this year were trained at Reading University. Moreover, this college has produced two R.H.S. Gold Medallists quite recently, so well as other N.D.H. successes. Mr. Bain also states that facilities for scholarships, etc., are not sufficient. May I remind him of the Ministry of Agriculture's scholarships, entitling young gardeners to tuition and residence at farm institutes, colleges and universities for periods of from three months to three years. Also of the many County Council scholarships and grants for tuition at centres of instruction in various parts of the country. It is also suggested that the Royal Horticultural Society should organise correspondence classes for the thousands of young gardeners thirsting for R.H.S. and N.D.H. certificates and diplomas. May I point out, again, that the existing correspondence classes are already sufficient to meet the demands of the comparatively few gardeners who are really prepared to work and study hard for the various examinations open to the profession. I am personally coaching, at the present time, young men in America, India and the Malay States who will have to travel thousands of miles to take the necessary examinations for the N.D.H. That these men realise the value of such a qualification is undeniable, but there are others who, although they would like to hold diplomas and certificates, would not walk across the street to obtain the finest course of training it is possible to procure. The "something for nothing" attitude exists, not only among miners, but I fear is eating its way into a profession which, while it may not reward its adherents by high wages, at least offers many compensating advantages. *Wilfred G. Ibbett.*

——I have read with much interest the letters which have appeared in *The Gardeners' Chronicle* dealing with the need of education for gardeners. As a public school and university man, I should like to state a few plain facts. I have received a thorough general education, having won two prizes at school for good work, and also, in higher forms, having obtained several certificates in agriculture and allied subjects. I then entered a well-known university, where I attended a full two years' course in horticulture. At the termination of this period I obtained the university diploma, being placed in the first division. In addition to studying horticulture, both theoretical and practical, the following subjects were also taken : Botany, (including mycology and bacteriology), chemistry (including physics), book-keeping, horticultural entomology, surveying and geology. I think it will be agreed that this training is fairly wide and thorough. On coming down from the university, I entered a big private garden, where I have obtained over a year's practical experience. For the past four months I have endeavoured to obtain a post, in either a private garden or nursery, but have been unsuccessful. Mr. William Good, in your issue of November 23 (p. 411), states ". . . public parks and gardens have come into existence all over the country, and, through them, the need for well-trained gardeners remains. There are also many posts, both at home and abroad, open to men who have had a thorough training in horticultural work." I think I can claim to have had at least a fair, if not thorough, horticultural training, but where, may I ask, are the many available posts. The point now arises as to whether education is really needed in horticulture at all. It rather appears as if it were completely ignored by head gardeners and nurserymen : and this being the case, is it worth while for young gardeners to study for such examinations as the R.H.S. general examination, and the National Diploma in Horticulture ? Having passed the above examinations, what are they worth? Possibly the offer of a position at 25s. to 30s. a week. Is it worth it? *H. A.*

Lonicera nitida.—The notes appearing on this subject with regard to its adaptability, suitability and hardiness in various districts are very interesting, and show how careful one needs be to experiment with it before carrying out extensive schemes of planting. It invariably dies back in the London district. The most robust young stock of this subject seen by the writer was the surprising result of an experiment of planting rooted cuttings direct from the frames into new ground of very stiff clay, so stiff, indeed, that when the plants were moved the following autumn they were cut out in squares of clay. *H. G. K., Twickenham.*

John Cypher Memorial Fund.—Having been interested in this Memorial Fund from its inception, and studied the several lists of donations which have appeared in *The Gardeners' Chronicle*, it appears to me that while there has been a fair response from certain quarters, the rank and file of the horticultural craft have not had that opportunity of giving their shillings, which they would be reluctant to send personally to the Secretary, but which would be willingly given in a collection. May I, therefore, offer a suggestion which may appeal to many as proved at a recent meeting of gardeners I attended at Altrincham, where Mr. R. Greenfield was holding forth in his usual emphatic manner on "Gardeners: Past, Present and Future," and which, of course, brought forth the usual discussion, which he ended in a practical way by asking for a collection for the subject of my note. This particular Society is noted for its many activities, and the appeal was very favourably received, with the result that £1 18s. 7d. was collected, and will be further increased by means of a whist drive. If the various horticultural societies throughout the British Isles would follow this lead, I feel sure there would be great response, as everyone would have the chance to give as suggested, and help to perpetuate the memory of a great man. A further suggestion which, I think, would bear good fruit if carried out, is the provision of a collecting card to be used by secretaries and other interested parties, so that anyone could respond in a modest way, and the Societies concerned would be added to the list of subscribers. *Allan Falconer, Stamford Park.*

Beheading Brussels Sprouts—This alarming procedure was justified here this autumn, for, owing to the drought, the plants grew much taller than usual, and at the end of September showed no signs of forming "buttons." We were afraid they would bolt, so cut out the heads, which were used in the usual way. As a result of this treatment we have a grand crop of solid sprouts of excellent quality and just at the right season. This practice is usual in the Vale of Evesham, and explains why the growers are able to secure a maximum amount of large, firm Brussels Sprouts up to Christmas. The growers only reckon to pick two or three times before the plants are cleared. To a private grower the practice may seem useless, but where a maximum crop, in a given period, is wanted, it is an excellent method of securing it. Naturally, it should not be attempted where an extension of the crop into the late winter is desired. *G. H. Emmett, Taplow.*

Strawberry Leaves in December.—As the year is drawing to a close, a few remarks upon the beauty of Strawberry leaves may not be out of place. Plants of The Duke are two-and-a-half years old, and very prettily coloured; in fact, this variety takes pre-eminence as the best-coloured foliage Strawberry we have, the gold and red leaves being decidedly attractive at this season of the year. Even the leaf-stalks are bright, deep, brownish-red, and not on one side only, but every part of each petiole is coloured. Not all the leaves show the same intensity of colouring, nor do even the leaflets situated on the same petiole. Some are deep red, some bright yellowish-red, others yellow, while there are red and green, and green and yellow also. On the thin petioles the leaves are more brilliantly coloured; and this might be regarded as typical of The Duke, although it does not hold good in every case. Foliage of The Duke comprises withered, beautifully coloured, and fine, healthy, green leaves. On several plants green flower buds are showing; while from one or two trusses the petals have fallen, and immature berries have been produced, which in their proper season would have developed into good fruits. Sir Joseph Paxton is a vigorous growing variety, and the petioles of the leaves on many plants measure ten inches to over twelve inches long. The leaves and petioles which do exhibit colour are yellowish-red. On the whole, there is not so much colour and certainly not the redness found in other varieties. The young plants of Sir Joseph Paxton, set out about the middle of August, are splendidly healthy: each plant is furnished with six, seven or eight leaves, respectively, the larger ones resting on the ground; only the leaves on two or three petioles per plant have changed colour, the others are beautifully green, and many of them measure six inches across, while their petioles are four inches long. *D. A., Midlothian.*

Verbenas for the Rock Garden.—With reference to the recent note regarding the hardiness of Verbenas suitable for the rock garden (p. 403), the following note on varieties grown in a garden within nine miles of London may be of interest. In this garden the strong-growing and lovely V. venosa proved much the hardiest, appearing each spring for five years, without protection, not only where it had been planted, but also where it had freely seeded itself in the chinks of a crazy-paving path. V. radicans and V. Mahoneti, came next in point of hardiness, coming through most normal winters successfully. V. chamaedryoides proved more troublesome, and seldom could it be depended upon to come through even a "green" winter. It will often send up new growths in June from the apparently dead roots, long after all hope of its revival has been given up, but it is much better propagated by cuttings annually, as few care to wait until June for a plant to commence growth. *W.*

Grey Squirrels.—It was very interesting to read Mr. G. W. Stracey's paragraph on what I term one of the most destructive little animals to the horticulturist, *i.e.*, the grey squirrel (p. 451). I gave the grey squirrel a great deal of study during the eighteen months I was living in Little Gaddesden, Hertfordshire, where my work carried me over Ashridge, with its magnificent Beech and Oak trees. It is a fact that one could not walk more than a few hundred yards without seeing a grey squirrel which, in my opinion, has rather the appearance of our detested rodent, the rat, its tail being thin and long and quite unlike that of the beautiful English brown squirrel, which has a bushy tail, and is, so far as I am aware, quite harmless to our fruit crops, its menu consisting almost entirely of such things as Beech nuts and Acorns. The grey squirrel was imported from America into the south of England in the districts where the brown squirrel once thrived and has now been almost entirely wiped out. At the same time the brown squirrel was introduced into America, and I understand has practically wiped out the grey, and taken full possession of its domains; I am afraid the Americans have had the best of the bargain. During my stay at Ashridge, I discovered one brown squirrel who was a big, powerful chap apparently living all by himself and left alone by the greys, and appeared to be the one survivor (residents in the district informed me the brown squirrels used to be numerous) until, alas, one day I found brownie dead and his body badly mutilated; evidently he had been raided by the greys who had overpowered him by force of numbers. I can imagine he put up a very plucky fight. The grey squirrels, apart from robbing gardeners, are notorious poachers of eggs and chickens of game and domestic poultry, and worse than all, I have known the grey squirrel to strip young trees of their bark, with the result that unless treated quickly, the tree is killed in a very short time. *L. A. Huddart, 32, Upper Tichborne Road, Leicester.*

Gentiana sino-ornata.—I am exceedingly glad that my request for information regarding the disease which is stated to attack this glorious Gentian has elicited some valuable correspondence. No one can think more highly of G. sino-ornata than I do, and it is most desirable to discover, if possible, the cause of any difficulties which may arise regarding its successful cultivation. I especially welcome the experience of Mr. W. E. Th. Ingwersen (p. 442) as helping to throw light, not only upon the probability of excessive sunshine being the cause of the fungus, but as also dealing with the question of propagation. I think it is quite probable that G. sino-ornata may appreciate the climate of Scotland better than that of the south of England, and, so far, I have no information that the fungus disease has appeared in Scottish gardens. I am growing it in lime-free soil and in a rather stiff, clayey loam in one place, and in a lighter soil in several other positions. In two places the exposure is one in which the Gentian receives a little sun in the morning and again in the late afternoon, and there is no appearance of any disease. I have three other lots which receive a good deal more sun, although not so early in the day as the others and, here again, no disease is present. It is just possible that the presence of lime, associated with much sun, may be injurious to G. sino-ornata, but this question of lime in association with certain plants is an extremely difficult one, and the more one learns of it the less does one care to dogmatise on the point. *S. Arnott.*

Bullfinches.—During the severe spells of cold weather experienced in 1928-29, I feel sure that fifty per cent. of the bird life was killed in this district. On the face of it this seems rather hard, but perhaps, after all, it is a wise provision of Nature, as I have noted with alarm the great increase in birds which attack our fruits and buds. It is to be regretted that such birds as blackbirds and thrushes, which delight us so much with their song, should be killed, for it is an easy matter to protect fruit from their raids. One bird, however, I am pleased to note, is less numerous this year, and that is the bullfinch. In recent years bullfinches have increased tremendously, and I think the failure of the Plum crop can be attributed more to them than anything else. They do their work with a stealth and thoroughness that is extraordinary. In the large wild garden here there are hundreds of trees of Prunus Pissartii, Amelanchier, Cerasus, Pyrus species and Loniceras. All these things they are fond of, and sometimes the trees are absolutely denuded of their flower buds. During the winter of 1927-28, I bought two sacks of Coco-nuts which were all consumed during the winter, but I never saw a bullfinch touch them. Swarms of the tit family, however, ate them, and it was interesting to watch their acrobatics. I have proved that all the tit family do a great deal of good, and rarely attack buds. So I advocate ruthless attack on all bullfinches; shooting with a B.S.A. air rifle is the best—a good marksman can kill a lot, and they hate the "zip" of the pellets around them. I know plenty will think me cruel to kill a pretty bird, but its monotonous pipe is not worth hearing, and as a bird it is not nearly so pretty as a cock pheasant, which is killed and eaten in large numbers. I might add, that I have tried things advocated in these columns from time to time, such as blue rags, tins and fat, but I have proved them to be all useless as scares against the bullfinch. If the birds are reduced in numbers, as I think they are, we should see a good crop of stone fruits next season, no matter what the weather may be. *Frederick Berry, Moreton Paddox Gardens, Warwick.*

Mushroom Growing.—I wonder if your readers could help me in a difficulty about Mushroom culture? I am seeking information as to the various methods by which they can be grown. I am well aware of the universal method of growing Mushrooms in hot-beds of manure made up as flat beds and ridges. This is the method I practise. I am trying to discover other ways. I have searched past records but find very little has been written about this valuable crop. Is it possible to grow them on hot-beds of leaves in a special compost, or in beds of compost heated by hot water ? Perhaps there may be some old forgotten method of growing Mushrooms which your readers know of. I would be very grateful for information. *F. Faires.*

FOREIGN CORRESPONDENCE.

DELPHINIUMS IN NEW JERSEY.

THE recent note on Delphiniums (p. 325) arouses a responsive chord, but we in the Eastern United States are unable to emulate your successful culture of these plants, except perhaps along the extreme north Atlantic sections. In the North-West, the conditions are more suitable. I do not mean we in the East cannot grow good Delphiniums, but we cannot handle named varieties, for the simple reason that rooted cuttings or divisions do not possess the vigour of seedlings, and to ensure good results it is necessary to raise new batches of plants from seeds annually, as it is rarely that the plants carry on beyond the second year. Happily, the English breeders have so improved their strains that we can get a wonderfully high percentage of fine types. Some good American strains of seeds, all, I expect, derived from English sources, are available but I have not seen any that compare with the Blackmore and Langdon seeds obtained direct, and I hazard the guess that hundreds of keen gardeners here send to England for their Delphinium seeds. A few plant firms do, I believe, save some seeds for their own use, and quite recently I saw a batch of plants that was claimed to be from home-saved seeds, that was almost 100 per cent. good, some plants being equal to some of the named sorts I can recall, although none possessed flower spikes three feet in length and ten inches across the base, as I have seen reported upon at English shows in recent years. I have raised numbers from north-west American-grown seeds, the germinative qualities of which are high, but the strongest have usually been too soft in the stem to hold up the spikes and the percentage of choice flowers has been rather low. I have, at the moment, a nice batch of seedlings of what is claimed to be a wonderfully fine strain, and I shall interestedly watch its performance against the Blackmore and Langdon strain.

The great bugbears of Delphinium culture in this section of America are leaf blight and root rot. The leaf blight appears quite early in the season, although some plants are not affected until the flower buds show. The foliage is largely blackened, the buds also, and if not checked the flowers fail to develop. This blight is due to a mite and by persistent spraying with nicotine it can be checked, but it is an awful business when a large number of plants is grown and there is a lot of other work to be done.

Root rot just snuffs off the plants in a day or two and it usually comes when they have reached the flowering stage. So far, I have not mastered this rot, which I believe is largely brought about by the acidity of my soil, the land being formerly Oak woods. Azaleas and Rhododendrons grow especially well as a result of this, but for some other things it is not so good and liming has not, so far, improved matters. *T. Weston, New Jersey, U.S.A.*

A FURTHER NOTE ON THE BLACK DOT DISEASE OF POTATOS.

ATTENTION was drawn in *The Gardeners' Chronicle* of December 29, 1928, to the presence of the sclerotia of Colletotrichum atramentarium on Potato tubers in this country, and more records of the prevalence of the disease have been published since, elsewhere, viz., in the *Journal* of the South-eastern Agricultural College, Wye, 1929, pp. 165 and 167, where a case of a forty-acre field of King Edward is recorded, and three instances are given where the fungus was causing damage in association with the eelworm Heterodera Schachtii.

In the more important literature on this disease, Dickson (Canada) describes the result of planting "seed" Potato tubers infected with numerous sclerotia of Colletotrichum atramentarium in experimental plots out-of-doors.

Concerning the plants, he states, "The plants grew poorly ; they were stunted and weak, and showed all the symptoms of dartrose. By September 18, the tops were dead, while adjoining rows were full of green tops."

A partial repetition of the experiment is included among some pot experiments at Kirton, Lincolnshire, and a progress report on the 1929 results may be of interest, since Colletotrichum atramentarium, on the strength of Dickson's description of this stunted and weak growth, is rapidly becoming included in the discussions upon "Potato sickness."

Seven earthenware flower pots (ten inch) of autoclaved soil were prepared and planted with King Edward tubers on May 1. No manure was applied. Series A, consisting of four pots, were planted with King Edward tubers infected with sclerotia of Colletotrichum atramentarium. Series B. (control) consisting of three pots, were planted with healthy tubers.

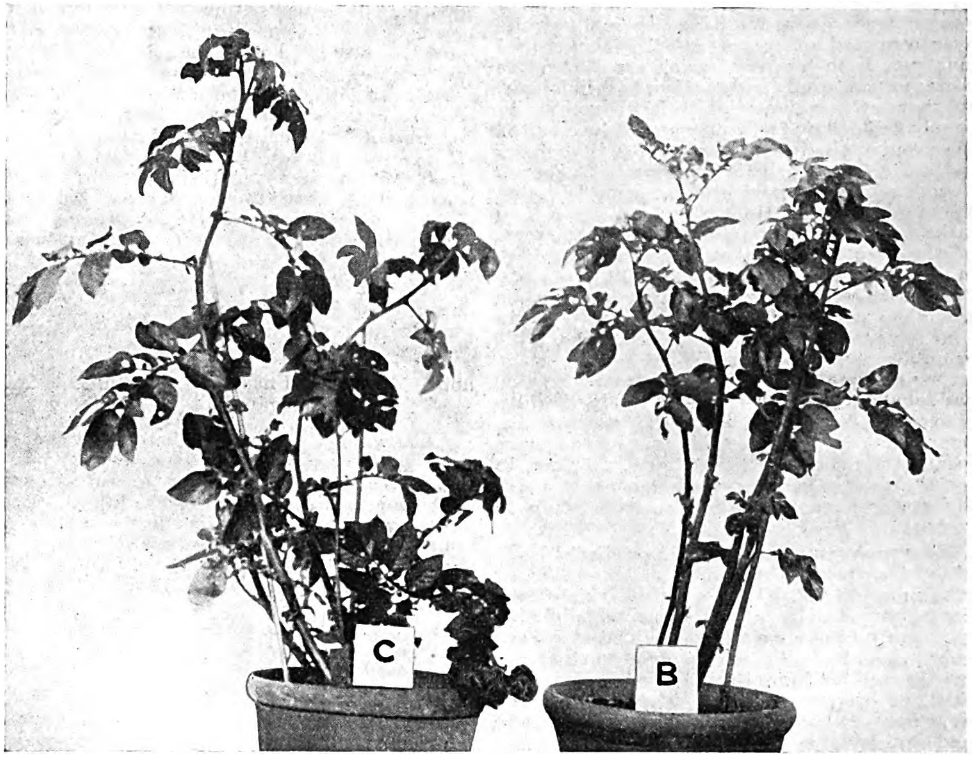

FIG. 229.—BLACK DOT DISEASE OF POTATOS.

C (Series B), healthy seed sets ; B (Series A), seed sets infected with Colletotrichum atramentarium. Photographed on August 14.

The plants, except for occasional waterings, were kept under outdoor conditions ; low temperature was experienced in the early part of the season.

The growth made by Series A was absolutely normal, and compared with Series B there were no signs of weakness or stunted appearance (Fig. 229 ; photograph taken August 14). At the commencement of the third week of August, although the plants must have been suffering by their abnormal pot conditions, the haulm was perfectly green. One plant of Series A was lifted, and it was possible to retrieve the old "set" for examination. Colletotrichum atramentarium was abundant on the skin and the black sclerotial bodies were also present in the decaying mush. Any doubt was dispelled that the fungus on the "seed" tubers had failed to grow.

The sclerotial bodies were observed on one or two dying stems of Series A by August 28, but the pot conditions caused Series B (control) to die down with equal rapidity, and for that reason further records of the effect of the disease could not be taken.

The preliminary experiment showed that weak and stunted plants such as were observed by Dickson under Canadian field conditions were not produced by growing King Edward seed Potatos infected with Colletotrichum atramentarium in sterilised soil, under the outdoor conditions of Lincolnshire in 1929.

I am much indebted to Dr. Pethybridge for the loan of literature. *W. F. Cheal, Kirton Agricultural Institute.*

THE TRAGEDY OF HARD PRUNING.

IN private gardens in this country, both large and small, there are hundreds of Apple trees which bear testimony to what may be described as the abuse rather than the judicious use of the pruning knife. Every year these trees produce a crop of young shoots along the main branches; these are promptly cut off in the annual pruning operation, only, of course, to produce another crop which in turn is treated in the same way as the last, and so the process continues until the particular operator comes to the end of his career and someone else takes the work in hand. It may be observed that this excessively hard cutting, often referred to as spur-pruning, is confined to private gardens—the commercial fruit grower knows better—and its origin may possibly be traced to the old custom, which still prevails, of planting bush Apples in vegetable gardens alongside the walks, on the understanding that they must not be allowed to extend over the walk on the one side and the ground required for vegetable culture on the other. I am willing to admit that by skilful management in the matter of periodical lifting or root-pruning a tree may be kept within certain limits if desired, but this can never be done by spurring back the young shoots every year and doing nothing more.

I have in mind at the moment a garden in which there is a number of trees which have been treated in this well-known manner for more years than I can remember. The pruning has been done every year by the same man, who in the first place helped another to do it, and has gone on ever since taking off the annual crop of young shoots and waiting for another crop to grow before repeating the process. This individual, by the way, has the reputation of being an expert pruner, and in his spare time he undertakes to prune the trees of amateur fruit growers round about, which, needless to state, he treats in the same way. I venture to state there are hundreds of these orthodox pruners in the country. They probably acquired this habit of cutting when doing or seeing it done as boys or young men, and having accepted it as gospel, they have adhered to it ever since without ever asking themselves why they do it, or what would happen if they allowed the tree to grow more as nature obviously intended it should ? If this rule of thumb habit of pruning were good—and after all it is little more than a habit—it is not unreasonable to ask why the commercial grower does not adopt it, who has to get his living out of his fruits. The only answer is that these annually hard-pruned garden trees do not produce so many fruits over a period of years as the commercial man gets from his trees which are allowed to grow more naturally and at a less cost in labour. In short, the commercial fruit grower would simply be heading for bankruptcy if he adopted the same method of pruning which is common in hundreds of private gardens. Of course, these hard-pruned trees produce some fruits on the spurs along the branches, and every year they make a dumb appeal to the pruner to leave some of the young wood they have made, which in due course would produce fruit buds and Apples, but no, that would be upsetting a system which has become little else but force of habit. This force, too, has become so strong that little or no discrimination is made between varieties, strong-growers and weakly growers are treated the same, as also are those the habit of which is to produce fruit buds at the ends of the young shoots. In fact, it is not too much to state that the pruning knife, as used in many private gardens, is a means of reducing rather than increasing the crops of fruits grown.

For some years past, I have been in the habit of regularly passing two villa gardens containing a number of bush Apple trees which were annually pruned by the same old jobbing gardener by the only method he had ever been taught, and he had never troubled to think the matter out for himself. The trees were mere thickets of young shoots when he started, they were skeletons of main branches when he had finished, and the young twigs strewn thickly on the ground came in handy for flower stakes. Then the house to which one of the gardens belonged became vacant and remained unoccupied for a considerable time, which meant that the trees were not pruned, but just left to grow. As a matter of fact they have never been pruned since, beyond removing some of the over- crowded branches, but this is the point, they have produced far more Apples than the trees in the other garden which have been treated religiously to the same annual cropping of the young shoots by the old gardener.

After all, the business of an Apple tree is to produce fruits, and commercial fruit growers have proved beyond question that the way to make a profit is to shape the tree in its early years and then let it grow very much as nature intended it should. Surely this should be the test—the yield of the tree and the cost of production in relation to labour. I am disposed to emphasise the latter consideration when I think of the hours and hours that are spent every year in snipping off the crop of young shoots from fruit trees, which is commonly called spur pruning. For years it was an accepted orthodox process, which may be the main reason for its survival ; old fruit growers defended it, old books describe it in details which are almost bewildering, and it was not until the commercial grower came along with his living to get out of fruits that a more rational use of the pruning knife came into vogue. It may be claimed, I think, that the commercial method of training and pruning trees is equally adapted to private garden culture, provided that when the trees are planted they are given room to grow and develop. *G. H. H.*

VEGETABLE GARDEN.

SALSIFY AND SCORZONERA.

ALTHOUGH only occasionally met with in gardens now, where a variety of produce is appreciated and desirable, Salsify and Scorzonera may advantageously be included in a comprehensive collection of vegetables and esculents, coming into season as they do at a time when a change of vegetables taxes the resources of the grower. The cultural requirements of both are so limited that no gardener need be deterred from giving them at least a trial.

I am of the opinion that, in common with other lesser-known occupants of the vegetable quarters, it is not so much a question of the gardener's skill to produce them as a test of the cook's ability to prepare the dishes in such a way as to bring out all the good qualities of the particular subject. It has been the writer's own personal experience that, after bringing to perfection such delicacies as Aubergines and Maize—to mention but two—the results of such labour was nullified by the inability of the kitchen staff to prepare the dishes for the table. All this is in passing, but I make bold to assert that it is the unfortunate experience of a goodly number of colleagues.

I propose to treat of Salsify (Tragopogon porrifolius) and Scorzonera (S. hispanica) together, as although they belong to different genera—albeit of the same Natural Order (Compositae)—the cultural requirements, and to a more or less degree the culinary process, are sufficiently identical to allow of this.

Neither of them is fastidious as to soil, and any good, deeply cultivated medium should be found suitable. There is no necessity to apply a dressing of manure if the crops follow one that was generously treated in this respect the previous season for, in common with the majority of root-producing vegetables, Salsify and Scorzonera fail to produce the clean, straight " thongs " (so desirable in esculents of this type) when allowed to come into contact with freshly-applied manure. Should the ground be at all poor it should be trenched deeply, incorporating suitable manure with the bottom spit only.

Seeds of both subjects may be sown any time during April or May, either at one sowing, or on two or three different dates for succession, although one sowing is usually sufficient for an average establishment. Draw drills fifteen inches apart and one inch deep, and sow the seeds thinly. I personally prefer the system sometimes advocated for Parsnips, Beet, etc., of placing three or four seeds the correct distance apart in the rows, in this case nine inches to one foot—the latter distance for Scorzonera—as a great saving both in seeds and labour is thus effected.

Thin the seedlings to one per station so early as practicable, for it will be found most difficult to effectually pull out the seedlings not required if they are allowed to remain too long, particularly with Salsify.

The routine treatment merely consists of a frequent use of the hoe to keep down weeds, taking care not to delve too deeply near the roots, or forked roots may result.

The roots should be of sufficient size to be available for the table early in November and may be lifted as required, although should severe weather conditions prevail, sufficient of the crop should be secured for immediate use, and it might be considered advisable to lift the whole after the turn of the year, storing them in sand and dry ashes in any cool shed or cellar. The roots should be inspected periodically and have all the young growths rubbed off. *T. Wilson.*

SOCIETIES.

SMITHFIELD CLUB.

EVER since it was instituted one-hundred-and-thirty years ago, the Annual Show of the Smithfield Club has stood for the best livestock the world can produce. It has been contended that the British farmer is the most conservative of men, who believes that what served his grandfather is the best for him. Like so many accepted sayings, this, of course, has no foundation in fact, and is a libel. No one who has visited the Smithfield Club Show over so long a period as we have could fail to be impressed by the changes that have taken place with all and nearly everything connected with our premier industry. Not only was this fully evident in the really wonderful machinery which is now part and parcel of the modern farm, but in the very beasts themselves that were shown in the Agricultural Hall, Islington, during the past week the change is fully evident. True, there was one Devon steer which with another hundredweight of solid flesh would have scaled a ton, but this was an exception, and no longer is to be seen the many ponderous fatted cattle of yester year. Such are no longer profitable, so the farmer breeds and feeds the animal which will provide the " baby beef," which the consumer demands.

Once again the show lacked the genial presence of our King, who was wont to visit the show and inspect the cattle, sheep and pigs with knowledge and understanding. But, happily, there was no untoward reason this year and all were able to rejoice in His Majesty's many successes at the show with unmixed feelings.

But, while we enjoyed more than a passing interest in the prize-winners, and others not so fortunate, our real business was in the gallery, for there were the exhibits of many of our most important seedsmen. While these, for the most part, are of the agricultural crops which form an exceedingly important branch, yet the exhibitors were not unmindful of the garden, which is a necessary adjunct of the farm.

In their accustomed place, Messrs. SUTTON AND SONS set out their expected display of gargantuan roots of such perfect shape that they might well have been moulded. But fine as were these perfect specimens of Mangolds, Turnips and Swedes, they gave pride of place to the immense Drumhead Cabbages, each of which were literally the size of an infantry big drum. Although so immense, these Cabbages, of the type known to the older school as Flatpoll, were perfect in their spherical shape, and were as firm as it is possible for a Cabbage to be. But these are of value to the farmer, while for the garden there were seasonable, and almost out-of-season vegetables of superb quality. Of the latter may be mentioned Tomatos Best of All, Every-Day, Golden Perfection and Golden Queen, and Mushrooms. Brussels Sprouts were represented by the large buttons of the variety Fillbasket. In sharp contrast to the Kohl Rabi which is grown as a farm crop, were the delicate samples of Sutton's Earliest White and Earliest Purple, which had an exceedingly tempting appearance. Among the excellent roots were Sutton's Favourite Intermediate Carrot, Globe Beet and Parsnips of the desired medium size and perfect shape, while there were selections of Onions and milk-white heads of Autumn Protecting Broccoli. Potatos which are even more important at this than at most shows, were represented by such sorts as British Queen, Arran Comrade, White City and Snowdrop.

For several years past, Messrs. E. W. KING AND CO. have shown a very desirable Beet in their New Intermediate, and also Dark Red Beet. Other vegetables of merit were Perfection Brussels Sprout, Greentop Stone Turnip, Offenham Parsnip and White Spanish Onion. Their best Potatos were The Bishop, Red King, Arran Comrade and Majestic. Messrs. JOHN K. KING AND SONS set out many good Potatos, Onions, Brussels Sprouts, Carrots, Turnips, and other vegetables, all in grand condition.

Associated with the superb Mangolds and cattle Turnips so imposingly arranged by Messrs. JAMES CARTER AND Co. were the long, fleshy stems of Marrow Kale, which rivalled the Jersey Kale in length, but far surpassed it in food value. Their Monster Drumhead Cabbages were monsters indeed of the Cabbage world. Chief among their garden vegetables were Carter's Autumn Protecting Broccoli in large heads of perfect whiteness; Holborn Leeks of the best exhibition size and form; Goliath Brussels Sprouts nearly as large as baby Cabbages; Maltese Parsnips and Standard Bearer Celery. Among the many good Potatos were dishes of Majestic, White Arran Victory, Eclipse, Catriona, Mr. Bresse, Di Vernon and Arran Victory.

The samples of Marrowfat Parsnip on the stand of Messrs. E. WEBB AND SONS betokened an excellent strain of this root, while their round-shaped Reliance Beet was also admirable. Well-grown Primula sinensis graced the stand which, on the agricultural side, included particularly good roots of Sugar Beet Southampton Champion. James's Longkeeping and Cranston's Excelsior Onions. Onions were very prominent on the stand of Messrs. TOOGOOD AND SONS, who also showed Crimson Beet, an attractive globe-shaped variety. Their vegetables were attractively "garnished" with boxes of fresh, green seedling Grasses.

Messrs. BLATCHFORD, LTD., had good selections of agricultural vegetables, and particularly good Brussels Sprouts. Mr. HERBERT J. SPEED set out good sticks of Celery, Brussels Sprouts, Carrots and Beet. Messrs. GARTONS had very attractive herbarium specimens of their pedigree Wheats and a number of very good transparencies of scenes in their grounds. Mr. HERBERT PARKER showed interesting and instructive herbarium specimens of various Grasses.

The little pyramids of Forex Brussels Sprouts on the stand of Messrs. HARRISON AND SONS drew attention to the merits of this variety. They also set out samples of Early Market Carrot, Leicester Pink Celery, Ailsa Craig Onions, heads of excellent Broccoli and many dishes of splendid tubers of the best varieties of Potato.

Fruits rarely assume any great importance at the Smithfield Club Show, and the present occasion was no exception to the rule, although Messrs. SEABROOK AND SONS showed splendid boxes of such Apples as Cox's Orange Pippin, Worcester Pearmain, Monarch, Bramley's Seedling, King of the Pippins and Newton Wonder, and also had sample young trees of various Apples, Pears, Plums, Damsons and Currants. Messrs. DICKSONS showed admirable dishes of various Apples, including the varieties Sandringham, Lane's Prince Albert, Cox's Orange Pippin, A. W. Barnes and Charles Ross. Mr. T. A. SCARLETT again showed sturdy three-year-old bushes of his Edwina Black Currant and excellent dishes of various Potatos.

As might be expected, Potatos are always an important feature of the exhibits in the gallery, and a great many varieties are shown. Messrs. FIDLER filled their customary place with an extensive collection which included the varieties Duke of York, Arran Chief, King Edward VII, Majestic, Mein's Early, Factor and Arran Banner. Other exhibitors of seed Potatos were Messrs. GUNN AND SONS, Messrs. JOHN MACKENZIE AND Co., Messrs. PATULLO, HIGGS AND Co., LTD., Messrs. JAMES GARDINER, Messrs. KENT AND BRYDON, LTD., Mr. W. J. REID, Messrs. WOTHERSPOON, DONALD AND GEORGE GRAHAM, Mr. R. W. GREEN, Mr. WILLIAM ROBERTSON, Mr. THOMAS McCLUNG, Mr. JOHN A. GRANT, Messrs. W. DENNIS AND SONS, Messrs. S. THOMPSON AND SONS, Mr. W. J. CAMPBELL, Messrs. W. AND R. GRAHAM, LTD., Mr. FRED MARSHALL, Mr. JAMES GRAY, Messrs. R. AND S. PATON, LTD., Mr. ISAAC POAD, Messrs. ROBERT MORRISH AND SONS, Mr. GEORGE WHITE, Messrs. THYNE AND SON, and Messrs. J. E. ENGLAND AND SONS. The MINISTRY OF AGRICULTURE OF NORTHERN IRELAND had a special stand, where they set out a few dishes of seed Potatos, and the names of certified growers of immune varieties.

HITCHIN CHRYSANTHEMUM.

THE exhibition of this Society, held in mid-November, was particularly successful but, unfortunately, the Town Hall does not provide sufficient space for the proper arrangement and display of the many fine exhibits staged by numerous clever and enthusiastic competitors. Sir C. Nall Cain is the President, and Mr. T. Pateman the Chairman of Committee, while Mr. W. G. P. Clark, the veteran amateur exhibitor, continues to act as Secretary, but is now assisted by Mr. J. G. Rusted.

About eighty classes were provided. In the cut flower division, chief interest centres in the class for six vases of Japanese varieties, three blooms of each variety, and here the principal award is a Challenge Cup valued at twenty guineas. On this occasion there was a distinct falling off in the competition, but not in the quality of the blooms, for Mr. B. FRANKLIN, Chesfield, Stevenage, won the Cup with splendid examples of Louisa Pockett, Birmingham, Majestic, Yellow Majestic, T. W. Pockett and Red Majestic. In the succeeding class, for four varieties, Japanese, three blooms of each, a smaller Silver Challenge Cup accompanies the premier award, and this was won by Major W. SHERIFF, Essex Road, Stevenage, who staged Yellow Majestic, T. W. Pockett, Majestic and Red Majestic; second, REGINALD ALASMIR, Esq. (gr. Mr. C. Wren), Woodlands, Hertford.

The best half-dozen Japanese blooms, distinct varieties, in vases, were shown by Mr. FRANKLIN, whose best flowers were of T. W. Pockett, Charles Davis, Princess Mary and Majestic; second, E. MARTIN SMITH, Esq. (gr. Mr. J. J. Mills), Codicote Lodge, Welwyn.

Single varieties were very well shown and the competition was very keen. For six vases, E. MARTIN SMITH, Esq., led, with Juno, Red Molly, M. J. Harris, Mrs. Palmer, R. Collins and Rose Molly; second, F. RANSOM, Esq.; third, Major J. F. HARRISON.

Dr. W. P. GRELLET showed the best four vases of Single Chrysanthemums, and his varieties were Juno, Lady Astor, Molly Godfrey and Catriona; second, W. G. WILLMOTT, Esq.; third, H. R. GRELLET, Esq. W. G. WILLMOTT, Esq., showed the best vase of Single Chrysanthemums in a close competition.

For six vases of Decorative Chrysanthemums, F. RANSOM, Esq. (gr. Mr. W. Robins), Newlands, Hitchin, led, with a capital display of George Carpenter, Edward French, Cranfordia, Lady Brunton, Rayonnante and Snowstorm; second, LADY WHITEHEAD.

The best three white Japanese blooms, one variety, were shown by Mr. FRANKLIN, who had grand flowers of Louisa Pockett; second, LADY WHITEHEAD, with Victory; third, E. MARTIN SMITH, Esq., with Nina Brown. LADY WHITEHEAD led for three blooms of a coloured variety, with Mrs. B. Carpenter; second, E. MARTIN SMITH, Esq., with Yellow Majestic.

The exhibits in the class for a vase of large Japanese blooms, arranged for effect, were not of the best, but possibly they had to be moved several times to provide extra space for other things and thus became somewhat disarranged. R. ABEL SMITH, Esq., won the first prize with yellow, white and pink flowers; second, LADY WHITEHEAD; third, R. W. OLDHAM, Esq. (gr. Mr. S. Kellaway), Carey Friars, Hitchin.

The best group of Chrysanthemums was a handsome arrangement set up by Messrs. ABBOTT BROS., Hitchin, but Mr. RALPH CANNON, who won second prize, also had a fine exhibit.

In the class for a table of cut Chrysanthemums, to represent not fewer than four of the sections of the flower there were several exhibits that were somewhat spoiled by overcrowding and rendered comparatively ineffective because they were unavoidably placed too closely together. LADY WHITEHEAD was awarded the first prize, and E. MARTIN SMITH, Esq., the second.

Major J. F. HARRISON (gr. Mr. A. J. Hartless), Kings Walden, Bury, led for perpetual-flowering Carnations, followed by LADY WHITEHEAD.

Plants were good. LADY WHITEHEAD led for three plants in flower, with Gesneras, followed in order by J. HOWARD EASTON, Esq., with Salvias, and Major HARRISON, with Gesneras. F. RANSOM, Esq., showed the best Cyclamens; LADY WHITEHEAD the best Begonia Gloire de Lorraine, and also the best large-flowered, winter-blooming Begonias.

VISCOUNT HAMPDEN (gr. Mr. Gillings), The Hoo, Whitewell, secured the premier award and Silver Challenge Cup for a collection of fruits arranged on a space six feet by three feet, and did so with an attractive exhibit o Alicante Grapes, Charles Ernest and Pitmaston Duchess Pears, and Allington Pippin, Cox's Orange Pippin, King of the Pippins, Brownlee's Russet, Lane's Prince Albert and Bramley's Seedling Apples. Second prize was won by Mrs. CARL HOLMES (gr. Mr. W. J. Penton), The Node, Welwyn.

All the fruit classes were well filled, and the Apples showed high colouring. VISCOUNT HAMPDEN had the best set of three dishes each of dessert and culinary Apples, showing Cox's Orange Pippin, Allington Pippin, Monarch, Newton Wonder, Gloria Mundi and Hoary Morning; second, C. W. GURNEY, Esq. (gr. Mr. E. Burbridge), Henlow Grange; third, Major HARRISON. Mrs. CARL HOLMES and Major HARRISON were first and second, respectively, for three dishes of culinary Apples.

In the single dish classes for Apples, Messrs. W. J. SIMPSON, W. F. CARMION, M. PETTINGELL, and J. G. RUSTED were particularly successful prize-winners.

Vegetables are always shown well at Hitchin. In Messrs. J. Carter and Sons' class for a collection, the prizes were won in order of mention by LADY WHITEHEAD (gr. Mr. C. Carter); Major HARRISON and Mrs. CARL HOLMES. In the open class for six kinds, W. J. EMPSON, Esq., Gamlingay, led, and M. A. GRIMES, Esq., Harlow, came second. In Messrs. Sutton and Sons' class, Major HARRISON was placed first and LADY WHITEHEAD second.

Other leading prize-winners in the vegetable classes were J. HOWARD CARTER, Esq., and E. MARTIN SMITH, Esq.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE last meeting of the old year was held in the R.H.S. Hall on Monday, December 9, Mr. Charles H. Curtis presiding. Before commencing the business, the Chairman regretted he had to report the tragic death of their late colleague, Mr. W. Wesker, and moved that a vote of condolence be passed; this was carried by the members standing in silence.

Four new members were elected. Four members withdrew interest from their deposit accounts amounting to £13 8s. 2d. and two members over seventy years of age withdrew £63 16s. 7d. from their deposit accounts. The sum of £128 14s. 4d. was passed for payment to the nominees of two deceased members. The sick pay on the Ordinary Side amounted to £122 7s. 0d.; Distress Fund, £19 10s. 0d.; State Section Sick Pay, £94 12s. 8d.; Maternity Benefits, £5. The sum of £36 11s. 0d. was paid in grants to State Insured members, for dental and optical treatment, and twelve other cases were considered.

WIMBLEDON GARDENERS'.

A MEETING of the above Society took place at The Queen's Hall, Wimbledon, on December 4; Mr. A. Hosking presided, and the lecturer was Mr. P. E. Cross, of the John Innes Horticultural Institution, whose subject was "Greenhouse Plants."

Mr. Cross spoke of Victorian times, when glasshouses were filled with hard-wooded plants, and traced the changes that have taken place up to the present day, when soft-wooded plants are the vogue. He gave a detailed list of suitable plants for greenhouse culture and ample information as to their treatment. Mr. Cross has had considerable experience in greenhouse work, and his paper was very much appreciated by the many experts present.

Mr. Hosking congratulated Mr. Cross on his fine lecture, and a vote of thanks was accorded him.

Mr. E. **Abraham** exhibited a magnificently-grown Chrysanthemum plant, for which he was awarded a Certificate of Merit.

NATIONAL CHRYSANTHEMUM.

At the meeting of this Society's Floral Committee, held at the R.H.S. Hall, on Monday, December 16, a few novelties were forthcoming, but these few were so good that no fewer than five found favour in the eyes of the adjudicators.

Balcombe Sunray. *II.* 1*b*.—A medium-sized Decorative and market variety; the flowers are borne on long, slender, but wiry stems; golden-amber. Shown by Mr. A. G. **Vinten**, Balcombe.

Bébé Gerard. *II.* 1*b*.—This is a large Decorative variety, flattish, and with broad florets; clear lilac-pink of a very pleasing shade. A fine late variety.

Joan Higgs. *I.* 1.—A pure white Incurved variety of fine substance and good size; stem and foliage excellent. A sport from Autocrat.

Thanksgiving Pink. *II.* 1*b*.—An American variety with rounded firm blooms of rich rose-pink colour.

Lyonesse. *II.* 1*b*.—An elegant Decorative variety, but a trifle thin as shown. The official colour description is Indian-red; we consider it deep rich bronze heavily flushed with red. These last four varieties were shown by Messrs. **Keith Luxford and Co.**

ROYAL HORTICULTURAL.

The following awards have been made to the undermentioned vegetables by the Council of the Royal Horticultural Society, after trial at Wisley.

Long Beet.

Awards of Merit.

(3 and 4) *Cheltenham*, sent by Messrs. **Watkins and Simpson**, and Messrs. **Nutting**; (40) *Non-Bleeding*, by Messrs. **Zwaan and van der Molen**; (66) *Exhibition Brydon's*), by Messrs. **Hurst**; and (73 and 74) *Dell's Crimson*, sent by Messrs. **Barr and Sons** and Messrs. **Nutting**.

Highly Commended.

(7) Cheltenham Selected, sent by Messrs. **Cooper Taber and Co.**; (9, 10 to 14) Cheltenham Green-top, by Messrs. **Morris**, Messrs. **Finney**, Messrs. **Clucas**, Messrs. **James Carter and Co.**, Messrs. **Dobbie and Co., Ltd.**, and Messrs. **Zwaan and van der Molen**; (17) Cheltenham Greenleaf, by Messrs. **Harrison**; (18) Greentop Selected, by Messrs. **Dobbie and Co., Ltd.**; and (20) Greentop, sent by Messrs. **Sutton and Sons** (all alike). (15) Cheltenham Greentop, sent by Messrs. **Zwaan and de Wiljes**; (19) Greentop, by Messrs. **E. Webb and Sons**, and (21) Amsterdam Market, sent by Messrs. **Zwaan and van der Molen** (alike). (25) Northumberland Dwarf, sent by Messrs. **Nutting**; (75) Victoria, by Messrs. **Harrison**; and (26) Covent Garden, by Messrs. **Barr and Sons** (alike). (42) Non-Bleeding, sent by Messrs. **W. H. Simpson**. (45) Blood Red, sent by Messrs. **James Carter and Co.** (50) Exhibition (Veitch's), sent by Messrs. **R. Veitch and Son**, and (53) Dark Red Salad, sent by Messrs. **Daniels Bros.** (alike). (59 and 60) Purple (Dobbie's), sent by Messrs. **Dobbie and Co., Ltd.**, and Messrs. **Morris**. (63) Volunteer, sent by Messrs. **E. Webb and Son**; (64) Exhibition Black, by Messrs. **Stuart and Mein**, and (65) Black, sent by Messrs. **Sutton and Sons** (alike). (71) sent as Pragnell's Exhibition, by Messrs. **Hurst**.

NATIONAL CARNATION AND PICOTEE.

The above Society held its fifty-first Annual General Meeting at the new R.H.S. Hall, London, S.W.1, on Saturday, December 14, when there was a good attendance of members. The Council's 1929 Report (for nine months, as the Society's year now ends on September 30 instead of December 31) showed that the Society was in a flourishing condition and that the period under review had been very successful, with an addition of fifty members and affiliated societies, and a balance in hand of £70 as against £50 for the previous twelve months. The fifty-second annual exhibition held on July 18 and 19, in conjunction with the British Carnation Society was most successful and, notwithstanding the adverse weather conditions prevailing at the time, and last minute cancellations of entries, the space filled was much larger than on the initial joint occasion. The Society's thanks were accorded to the Hon. Secretary of the B.C.S., also to the R.H.S. officials for their whole-hearted co-operation.

It was intimated that another combined exhibition will be held in the old R.H.S. Hall, on July 15 and 16, 1930. The Hon. Secretary reported the gifts of three additional trophies for 1930:—The Lady Hudson Cup (open) for Clove-scented Carnations; the Abol Cup (open), to be won outright for twelve vases consisting of three Border Carnations, Clove-scented Carnations, Picotees and Pinks (any section), respectively, distinct varieties, three blooms or stems of each; and the Julia B. Wells Trophy to be won outright (amateurs only), for Picotees. It was intimated that the Society's publication, to be known in future as *The Carnation Annual*, would be issued in the New Year and would be a great improvement on previous issues and a book well worthy of the Society. At future exhibitions the Society's special medal will be awarded to all winners of cups.

The retiring President, Mr. Edmund Charrington, was unanimously re-elected, with the best thanks of all for his continued support and generosity. The following were elected on the Council for three years:—Messrs. T. J. Child (Catford), S. H. Gregg (Bowes Park), A. S. Hampton (Reading), H. A. Knapton (Orpington), A. E. Mustow (Worcester Park), and F. W. Seymour (Finchley). The Hon. Secretary, Mr. A. E. Amos, Hon. Assistant Secretary, Miss J. B. Wells, and the Hon. Treasurer, Captain E. M. Wilkinson, were unanimously re-elected with appreciatory thanks for past services. The new post of Hon. Show Superintendent was filled by Mr. T. J. Child (London), and Messrs. Howard, Morris and Crocker, of Portsmouth, were elected Hon. Auditors, while a hearty vote of thanks was accorded the retiring auditors, Messrs. Burnett, Burnett and Swayne, of Southampton.

GUILDFORD AND DISTRICT GARDENERS'.

The lecture on Tuesday, December 10, delivered by Mr. J. Coutts, Assistant Curator of Kew Gardens, was listened to by a large Company, many of whom had come a considerable distance and several members not ordinarily seen at meetings were attracted, probably as much by the standing of the lecturer as by his subject, "Rock Gardens"—which Mr. Coutts said was one of growing popularity and interest. In an attractive way the advantages of rock plants were set forth. A great many of the plants under consideration could be grown in a small space and quite a number of them on level ground, and while many were grown in conditions unlike their natural habitat, they were amenable to cultivation and would do well.

In making a rock garden a deep root-run is essential, for while a plant may only be a few inches high the roots extend considerably, some of them to two or even three feet. Sharp drainage is another necessary requisite; water must be moving, stagnant water being fatal. The site should be open and not surrounded by trees, and no bricks or clinkers allowed in the construction.

It was surprising the number of plants that could be grown in and around London. In arranging a garden the gardener should keep in mind the kind of plants he wants to grow. Considerable details were given as to methods of constructing rock gardens and the use that could be made of moraines, and suggestions made as to the plants to grow, especially Saxifraga, Campanula, Anemone, Dianthus and Primula. Stocks might be replenished by the aid of a few cold frames. The lecture was amplified by a number of lantern slides showing rock gardens in course of construction, and prize-winning exhibits at Shrewsbury and Southport Shows, together with a number of slides showing many plants thriving in the Botanical Gardens at Edinburgh, where some alpines which do not thrive at Kew can be grown successfully.

Other interesting points were brought out by questions raised by Mr. Joy, of Snowdenham; Mr. Turner, Albury Park; Mr. Blandford and Miss Twinn, West Horsley.

A vote of thanks was passed on the proposition of Mr. Blunden, seconded by Mr. Westlake, both of whom said they had enjoyed the lecture and profited by it.

Mr. Patrick, who presided, announced that the next meeting night, Tuesday, January 7, would be devoted to demonstrations by members of the Association—Mrs. Hammond, of Horsley, on "Table Decorations"; Mr. Newman, Tangley Place, on "Pruning Small Fruit Trees," and Mr. Joy, Snowdenham, on "Root-pruning."

ANSWERS TO CORRESPONDENTS.

A Variegated Phlox.—*T. L.* If your Phlox is of semi-decumbent growth, it is probably Phlox amoena var. variegata.

Early-flowering Chrysanthemums.—*Correction*.—In my epitome of the trial of early-flowering Chrysanthemums under the auspices of the National Chrysanthemum Society, at Cookham (see page 389), I inadvertently stated that "Hollicot Yellow" was synonymus with "Cranfordia." I should have stated with "Goldfinder"—the name it is often catalogued under: Hollicot Yellow is its proper name. This variety received three marks on September 24, last. *D. B. C.*

Finger and Toe Disease in the Garden.—*Digger*. Soils in which the above disease (Plasmodiophora brassicae) is prevalent are acid or sour owing to long-continued manuring and a deficiency of lime. The plan you propose to take is right. Ordinary quicklime is the best form to use after it is slaked. Slake it in a shed or under cover to prevent it becoming too wet by rain. It is easiest to spread equally in powder form. If the soil is light, a quarter-of-a-pound to the square yard would be enough, to avoid wastage of the humus; if it is heavy, half-a-pound to the square yard would not be harmful. In about a fortnight after application, the lime will have lost its caustic nature and become carbonate of lime or chalk again and it will be safe to sow or plant. The lime will take two or three years to have full effect in rectifying the sour soil, therefore a fresh application may be given in the fourth year.

Names of Plants.—*C. W. S.* The Rhododendron is R. Nobleanum (R. arboreum × R. caucasicum), a hybrid that usually commences to flower in December and continues, weather permitting, until March.—*B. H. C.* 1, Pelargonium ionidiflorum; 2, Mesembryanthemum violaceum; 3, Ruellia Portellae; 4, Polygoneum capitatum; 5, Pteris cretica var. Alexandrae; 6, Selaginella Braunii; 7, S. Emiliana; 8, Pteris longifolia; 9, Adiantum cuneatum var.; 10, A. Weigandii; 11, A. cuneatum var. grandiceps; 12, A. Capillus-veneris; 13, A. cuneatum var. gracillimum; 14 and 15, forms of A. cuneatum.

Shrubs for an East Exposure.—*R. G.* Plant a group of five plants of the new hybrid Berberises that are free-fruiting, *i.e.*, B. Comet, B. Sparkler, B. rubrostilla, etc.; and a group of five plants of Viburnum plicatum, or of the new purple-flowered Brooms, such as Cytisus Dorothy Walpole, C. Dallimorei and C. Donard Seedling.

Ramondia serbica var. Nathaliae.

Average Mean Temperature for the ensuing week deduced from observations during the past fifty years at Greenwich, 38·7°.

The Scent of Flowers.

With the pitiless December rains experienced lately, which make outdoor gardening impossible, what is there more pleasant than to read about the garden. Next to the catalogue, which is the true gardener's favourite study, descriptions of gardens give, perhaps, the most solace; who, for example, could not spend a pleasant hour and discover troops of awakened memories in reading or re-reading Dr. F. A. Hampton's charming paper on "The Scent of Flowers."* Most freakish of all the senses, smell is at once potent and elusive. The man of science who has much to tell us on all such subjects, imputes this freakishness to the variable state of degeneracy of the olfactory tract of our brains—and, of course, to our regular and liberal use of Tobacco. Let it be conceded that our sense of smell is not of the acutest—a mere nothing compared with that possessed by the dog, who puts up the intrusive rabbit at our feet and pursues its track unerringly and unsuccessfully across all our best flower beds. Nevertheless, although we may not possess—for better or for worse—the sharpness of scent of the hunting animal, it is sufficiently developed in most of us to make the well-planted garden a source of almost as much pleasure to our noses as it is to our eyes. For the odours of the garden come to welcome us—heralds of the pomp and glory of the summer day. So it is interesting to learn that we owe, perhaps, most of the fine and soft odours of the garden to the conspiracy which moths and flowers entered into long ages ago. There are flowers that smell unpleasantly and look no less unpleasant—these, the Stapelias and Privets and others, are in league with flies. To attract these creatures the flowers must needs acquire a carrion odour. Let us pass these by with averted noses. Then there are the multitudes of bright flowers, masses of colour which in like manner lay themselves out to captivate the bee so that by incessant visiting pollen shall be brought from one flower to the stigma of another of like kind. The bee, like most very busy people, is not very gifted. Its sense of colour is but partial, and hence it needs a lot to attract its notice. The bee's sense of smell is about as good as the average human being's, and is undoubtedly helpful in guiding it to the honey-scented Clovers and Limes and Gorse, and even as Dr. Hampton avers, to the deeply spice-scented Broad Bean and the delicately fragrant Sweet Pea. It is, however, among the flowers which made that old compact whereby moths should be the bearers of floral fertility that the exquisite odours of the garden are to be found. The moths, and in particular those that fly by night, have need of strong odours to guide them, lest they miss one another in the darkness and so become extinct. And so, hovering, they wave plumes like fans, in courtship, diffuse sweet odours as though "a box of essences were broken in the air." These odours which the night-flying moths scatter are like unto the odours of Jasmine, Honeysuckle, Musk, Vanilla and all those wonderful scents of the strikingly odoriferous flowers. So that—though heaven forbid—it would appear that the flowers with these exquisite scents have produced them to lure the moths away from their own love trysts to the cognate affairs of the flowers themselves. We shall imagine the joyous confusion of these night-flying moths when they discover on balmy evenings that the odours which whisper to them of love are everywhere. The cynical, who spoil everything, might aver that in this strange world of the night-flying moths and the night-blooming flower the *menage a trois* first "saw the light." Beside this splendid group of exquisitely scented flowers, there are other smaller and scarcely less interesting groups. Thus the flowers of Calycanthus floridus, brown in colour and suggestive of decaying fruit, attract the wasp, no doubt for that reason. It would be possible to linger much longer with pleasure and profit over Dr. Hampton's fragrant pages; to ask with him whether the true old Rose scent is found only among the pink, white and red Roses; whither has fled the true Musk odour of the Musk plant (Mimulus moschatus); and how it is that the musk scent of Wichuraiana Roses is confined to the stamens—or, as Parkinson stated it three hundred years ago, "the cheerful scent of these Roses consisteth not in the leaves but in the threads of flowers." And lastly, to chronicle the new or newer odour-bearing plants—the sweet-scented Viburnum Carlesii and V. fragrans, Hammamelis mollis, Osmanthus Delavayi and Lonicera syringantha; and to record the pleasant legend that the scent of Mentha citrata is the original scent of the world from which all others are derived; one so powerful that it will enhance the fragrance of any flower near it.

Our Supplement Plate.—On the occasion of the special show of alpine plants at Westminster, Mr. Mark Fenwick exhibited a wonderfully fine specimen of Ramondia serbica var. Nathaliae, and this is the subject of the Supplement Plate presented with the present issue. Mr. Mark Fenwick, Abbotswood, Stow-in-the-Wold, kindly sends the following note concerning this plant. "The plant illustrated is one of a batch of unpricked-off seedlings given me some ten years ago by Mr. Simpson Hayward, of Icombe Place. My gardener, Mr. Justin, who grows Ramondias extremely well, keeps them in a frame shaded from the sun in summer and never allows them to get dry at he roots. They are thoroughly moistened overhead, and all round the pans. The soil he uses is two-parts loam, one part leaf-mould and one-part peat."

"The Gardeners' Chronicle" Almanac for 1930.—The preparation of our Almanac for 1930 is now proceeding, and as we are anxious to include so many dates of horticultural exhibitions and meetings as possible, the secretaries of horticultural, botanical and kindred societies are invited to send us the dates of their fixtures for the coming year, to reach us on or before December 31, 1929.

Fifth International Botanical Congress (Cambridge, August 16-23, 1930).—By courtesy of the President and Council of the Linnean Society, a general meeting of British botanists will be held at the Society's Rooms, Burlington House, Piccadilly, W.1., at 3 p.m., January 10, 1930, when the Chairman of the Executive Committee will report the progress made in organising the Congress. All interested in the matter are invited to attend.

1929 Register of Growers of Certified Stocks of Potatos.—During the past season, Inspectors of the Ministry of Agriculture have examined over 8,000 acres of growing crops of Potatos with a view to certification if found to be true to type and reasonably free from rogues. Particulars of crops certified as reaching the required standard of purity of not less than 99·5 per cent. are given in the Register of Growers of Certified Stocks of Potatos in 1929, which has just been issued by the Ministry. Growers are reminded that, under the Wart Disease of Potatos Order of 1923, the only Potatos that may be planted in land on which Wart Disease has occurred at any time are Potatos of approved immune varieties, which have been inspected while growing, and certified as true to type and reasonably free from rogues, or Potatos of approved immune varieties saved from crops grown on the land in the previous year. The Order further provides that, on the sale of any Potatos for planting, the number of the relative certificate issued under the Order must be quoted. In the case of Potatos of approved immune varieties, the certificate number to be quoted is that given in the Register of Growers, but in the case of other varieties the number to be quoted is that of the relative Clean Land Certificate issued to the growers concerned, and not that of the Purity Certificate quoted in the Register. Copies of the Register of Growers may be obtained from the Ministry on application to its Offices at 10, Whitehall Place, London, S.W.1. Price 1s.

Gardens of England and Wales.—In its report for 1929, the Gardens Committee of the Queen's Institute of District Nursing states that through the great kindness of many owners, 690 gardens were opened between the months of April and September; a large number of these were open on more than one occasion, bringing the total of openings up to 939. The Committee greatly appreciates such a generous response from the owners to the appeal to show their gardens and is gratified to be able to report that the splendid sum of £7,765 was raised in aid of the work of the Queen's Institute of District Nursing and of District Nursing throughout the country. It is not possible to print a detailed list of the amount collected in each garden, but a list is appended showing what was raised in each county. It will be of special interest to see that His Majesty The King has sent £834 15s. from the opening of his gardens at Sandringham. The interest again taken in the scheme, not only in England and Wales, but also by overseas visitors, has been a great encouragement to the Committee; this shows that the scheme not only helps the work of District Nursing but is also a source of pleasure to those who visit the gardens :—His Majesty The King, Sandringham, £834 15s. 0d.; Bedfordshire, £51 16s. 0d.; Berkshire, 14s. 3d.; Buckinghamshire, £368 5s. 2d.; Cambridgeshire, £45 6s. 6d.; Cheshire, £287 8s. 0d.; Cornwall, £70 18s. 6d.; Cumberland, £15 11s. 10d.; Derbyshire, £170 0s. 9d.; Devonshire, £259 12s. 0d.; Dorsetshire, £504 18s. 11d.; Durham, £16 15s. 6d.; Gloucestershire, £254 16s. 6d.; Hampshire, £171 5s. 7d.; Herefordshire, £100 17s. 11d.; Hertfordshire, £128 6s. 0d.; Kent, £509 5s. 4d.; Lancashire, £359 13s. 2d.; Leicestershire, £48 12s. 0d.; Lincolnshire, £6 1s. 0d.; London, £44 15s. 0d.; Middlesex, £79 18s. 0d.; Monmouthshire, £40 11s. 9d.; Norfolk, £152 8s. 6d.; Northamptonshire, £30 8s. 0d.; Nottinghamshire, £130 6s. 10d.; Oxfordshire, £131 12s. 10d.; Rutlandshire, £16 2s. 3d.; Shropshire, £106 19s. 3d.; Somerset, £141, 16s. 0d.; Staffordshire, £43 18s. 9d.; Suffolk, £168 17s. 2d.; Surrey, £599 3s. 11d.; East Sussex, £454 14s. 11d.; West Sussex, £233 13s. 11d.; Warwickshire, £112 10s. 6d.; Westmorland, £31 10s. 6d.; Wiltshire, £249 2s. 7d.; Worcestershire, £39 8s. 0d.; Yorkshire—East Riding, £11 17s. 2d.; North Riding, £60 2s. 0d.; West Riding (including Small Gardens Scheme, 1928), £320 0s. 2d.; Wales—Anglesey, £202 14s. 9d.; Brecknockshire, £42 16s. 5d.; Carnarvonshire, £46 11s. 0d.; Denbighshire, £20 12s. 0d.; Glamorganshire, £29 5s. 6d.; Radnorshire, £4 1s. 0d.; Sundry Donations, £14 19s. 0d. Total, £7,765 17s. 7d.

---

* *Journ. Roy. Hort. Soc.*, Vol. LIV, Part I. January, 1929.

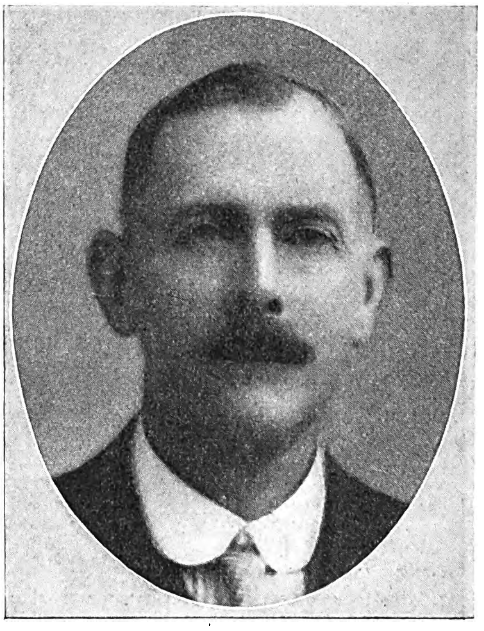
Mr. W. J. Bean.—We learn that Mr. W. J. Bean, who lately retired from the staff of the Royal Botanic Gardens, Kew, after forty years' service, has accepted the appointment of Adviser and Consultant on the planting on Highways to the Ministry of Transport. His duties will be to report on road-planting schemes, and the after-care of trees. He has also been appointed conjointly to the Roads Beautifying Association to visit and report on all planting schemes designed by its Technical Committee.

R.H.S. Examinations, 1930.—Prospective candidates for the examinations of the Royal Horticultural Society are reminded that the closing dates for entries for the 1930 examinations are as follows :—General Examination (seniors and juniors), January 13; Teachers' Examination (preliminary and advanced), January 13; National Diploma in Horticulture (preliminary and final), February 1; and Scholarship Examination, March 31. Entry forms and full particulars may be obtained from the Secretary, Royal Horticultural Society, Vincent Square, London, S.W.1.

French Chrysanthemum Congress.—On November 5, more than one-hundred-and-fifty Chrysanthemum growers assembled at Béziers, France, for their annual conference, presided over by M. Charvet, the President of the French Chrysanthemum Society. A number of questions were discussed, including means to prevent bud-drying, arsenic as a pest-destroyer, blossom-decay, diseases and parasites. A valuable medal was awarded to the contributor of the best paper, M. Fraigneux, of Neuchâtel, whose subject was "Diseases and Parasites." The Congress unanimously chose Geneva as the place of meeting for the Congress of 1930. The Society's Medal of Honour was awarded to M. Edmund Roucayrol, for thirty years a cultivator of Chrysanthemums in the south of France, and one of the pioneers in that industry. He edited the Society's propaganda leaflet, and took a considerable part in the organising of the Béziers Congress, and of the exhibition which accompanied it. Among the prize-winners at the latter were the following :—M. Henri Galinier, Béziers, Objet d'Art offered by the President of the Republic; M. Jacques Lemasson, Objet d'Art from the town of Béziers; M. Henri Cornette, gardener to M. Hennessy, at Cognac, Objet d'Art given by the journal *L'Eclair*; and the municipal gardeners of the town of Montpelier, a Silver-Gilt Medal from the Minister of Agriculture.

A New Botanic Garden for Massachusetts.—With the closing of the Harvard Botanic Garden, as announced in our issue of December 14 (p. 459), Massachusetts was left without a botanic garden, but this need has already been met by the establishment of a new botanic garden in the residential quarter of Lexington. The land acquired for this purpose is stated to be very fertile and mostly flat; it embraces about eleven acres and was formerly a market garden. The land is to be laid out in a series of gardens, each devoted to distinct subjects, and several glasshouses, including an unheated alpine house, will be erected. The work of laying out this new botanic garden has already commenced, and it is stated the testing of hardy plants will be carried out on a large scale. The garden will be open to visitors every day throughout the year.

Mr. J. Bond.—At the early age of twenty-four years, Mr. J. Bond was appointed gardener at Olantigh Towers, Wye, Kent; he continues in charge of this charming garden that contains a very fine collection of hardy fruits. During this period, Mr. Bond has served under two employers, W. E. S. Erle Drax, Esq., and J. H. London, Esq., the latter of whom has been in residence at Olantigh since 1913. Both Mr. and Mrs. London are keen gardeners and afford Mr. Bond every encouragement in his work. Mr. Bond has been a very successful exhibitor, winning prizes at Folkestone, Canterbury, Maidstone, Dover, and at the Royal Horticultural Society's exhibitions over a long period of years. Other successes with fruits have been won at the Imperial Fruit Show. Mr. Bond served as a lad at Pasbury House Gardens, Crediton, the residence of Lady Shelley, whose son conducted a market garden, where Mr. Bond gained a good training in the cultivation of Tomatos, Cucumbers, soft fruits and Marechal Neil Roses under glass. Further experience was gained at The Grove, Teignmouth; Holnest Park, Sherborne (then the residence of W. E. S. Erle Drax, Esq.), and Ashlyns Hall, Berkhamsted, before taking charge of the gardens at Olantigh Towers in 1896.



MR. J. BOND.

The Frankfurt Palm Garden.—The Palmengarten in Frankfurt, Germany, has undergone a considerable change this year. Meeting and dining rooms in the newest style have been created by remodelling the front of the great restaurant. These rooms are surrounded at the southern end with boxes, which are protected by glass, and filled with foliage and flowering plants in a very effective manner. One of the glasshouses is filled with stove plants, another with cool-house plants. The whole arrangement is of a very attractive character and affords visitors an opportunity of admiring beautiful plants while in the club rooms. The great Palm house and the plant show houses have been repaired and decorated so that the great damage sustained during the past fourteen years is no longer evident, and once more they contain valuable collections of plants.

Iris tingitana and Yellow Freesias.—Half-a dozen blooms of the beautiful Iris tingitana, borne on stout stems, and half-a-dozen spikes of a yellow Freesia, averaging eight flowers per spike, are brightening the editorial table this week. These were sent by Mr. James J. Staward, gardener to W. Ropner, Esq., Thorp Perrow, Bedale, who states that he commenced to cut flowers of both these kinds at the end of November, and expects to continue to do so regularly until the end of March. In each case the flowers were of fine size and substance, and admirable for floral decorations during the winter season.

Record Potato and Oat Crops in Scotland.—In the report of the crops produced during the past season, the Department of Agriculture for Scotland states that the estimated total yield of Potatos, amounting to 1,155,000 tons, shows an increase of 123,000 tons, or 11·9 per cent. The area under crop was about 145,000 acres, an increase of 700 acres compared with last year, and the yield was eight tons per acre, which is the highest ever achieved, the previous best figure being 7·6 tons in 1920 and 1922. The yield is also 1·5 ton greater than the decennial average. The standard natural weight of Oats (42 lbs. per bushel) was exceeded in Roxburgh, north-east Fife, Moray, south-west Banff, central Aberdeen, Kincardine, north-east Angus, south-east Perth and Stirling, while the standard weight was exceeded in fourteen other districts throughout the country. The estimated total production of Oats was 755,000 tons, an increase over last year's crop of 51,000 tons, or 7·2 per cent. The area under crop was greater by 10,295 acres, and the yield of 45·5 bushels marks an increase of 1·8 bushel compared with 1928, and of 5·4 bushels as compared with the average of the preceding ten years. Last year's yield of Oats was the highest then on record, and this year that record has been exceeded. The reports on Sugar Beet are generally favourable.

Appointments for the Ensuing Week.—Monday, December 30: National Chrysanthemum Society's Floral and Executive Committees meet. Tuesday, December 31: Royal West Renfrewshire Horticultural Society's meeting. Wednesday, January 1: Rotherham and District Horticultural Society's meeting; The National Carnation Society (Northern Section) meets; Gainsborough Allotment Holders' Association's meeting; Reigate and Redhill Gardeners' Association's meeting. Saturday, January 4: Leeds Paxton Society's meeting.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Coveney's Economical Manure.*—A ton of Coveney's Patent "Economical" Manure contains, according to Professor Apjohn's report of its composition, about 4 cwt. of plaster of Paris, 4 cwt. of Glauber salts, nearly 8 cwt. of green vitriol, and 2½ cwt. of common salt, together with 1½ cwt. of other things, which include 30 lbs. of sulphate of ammonia. Of course, these salts contain a large quantity of water—a mere useless addition to the weight of the mixture. The Glauber salts or sulphate of soda contains 55 per cent. its weight of water; the plaster of Paris, sulphate of lime, contains one quarter of its weight of water; and the green vitriol, sulphate of iron, 42 per cent. of water. In the case examined by Dr. Voelcker, this water amounted to more than 7 cwt. in every ton; the other ingredients in the dry state being—green vitriol nearly 5 cwt., bisulphates of potash and soda nearly 3 cwt., Glauber salts about 3 cwt., sulphate of ammonia about ½ cwt., together with 1½ cwt. of other things, chiefly sand. Excepting the absence of gypsum, and the greater quantity of ammonia present in the latter of these instances, they do not materially differ: the sulphuric acid, soda and iron being in both the principal and characteristic ingredients. *And, in themselves, and as direct applications, three less useful additions to ordinary English soils it would be difficult to select.—Gard. Chron., December* 30, 1854.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM GRANDE.

The specimen of Odontoglossum grande represented in the accompanying photograph (Fig. 230) was purchased by J. McCartney, Esq., Hey House, Bolton, as an imported plant, in 1922, at, I believe, a sale at Messrs. Protheroe and Morris's sale rooms. When I went to Hey House this plant was in a four-and-a-half-inch pot, and had only one lead; it now has thirteen leads. We grow Odontoglossum grande in the warmest part of the Odontoglossum house, and during the resting period very little water is given, but when the plants are in growth they are watered practically every day and sometimes twice a day in hot, sunny weather. The water we use is rain water, " with the chill off," but our water contains a good deal of soot brought down by the rains, for the atmosphere in Bolton is full of soot produced by the surrounding factories.

Within approximately a quarter-of-a-mile of Hey House there are no fewer than fifty factory chimneys. therefore readers will appreciate our difficulties in the cultivation of Orchids under such impure and uncongenial atmospheric conditions.

When it was photographed the specimen illustrated carried a total of ninty-one expanded flowers and five buds. *C. F. Potts, The Gardens, Hey House, Bolton.*

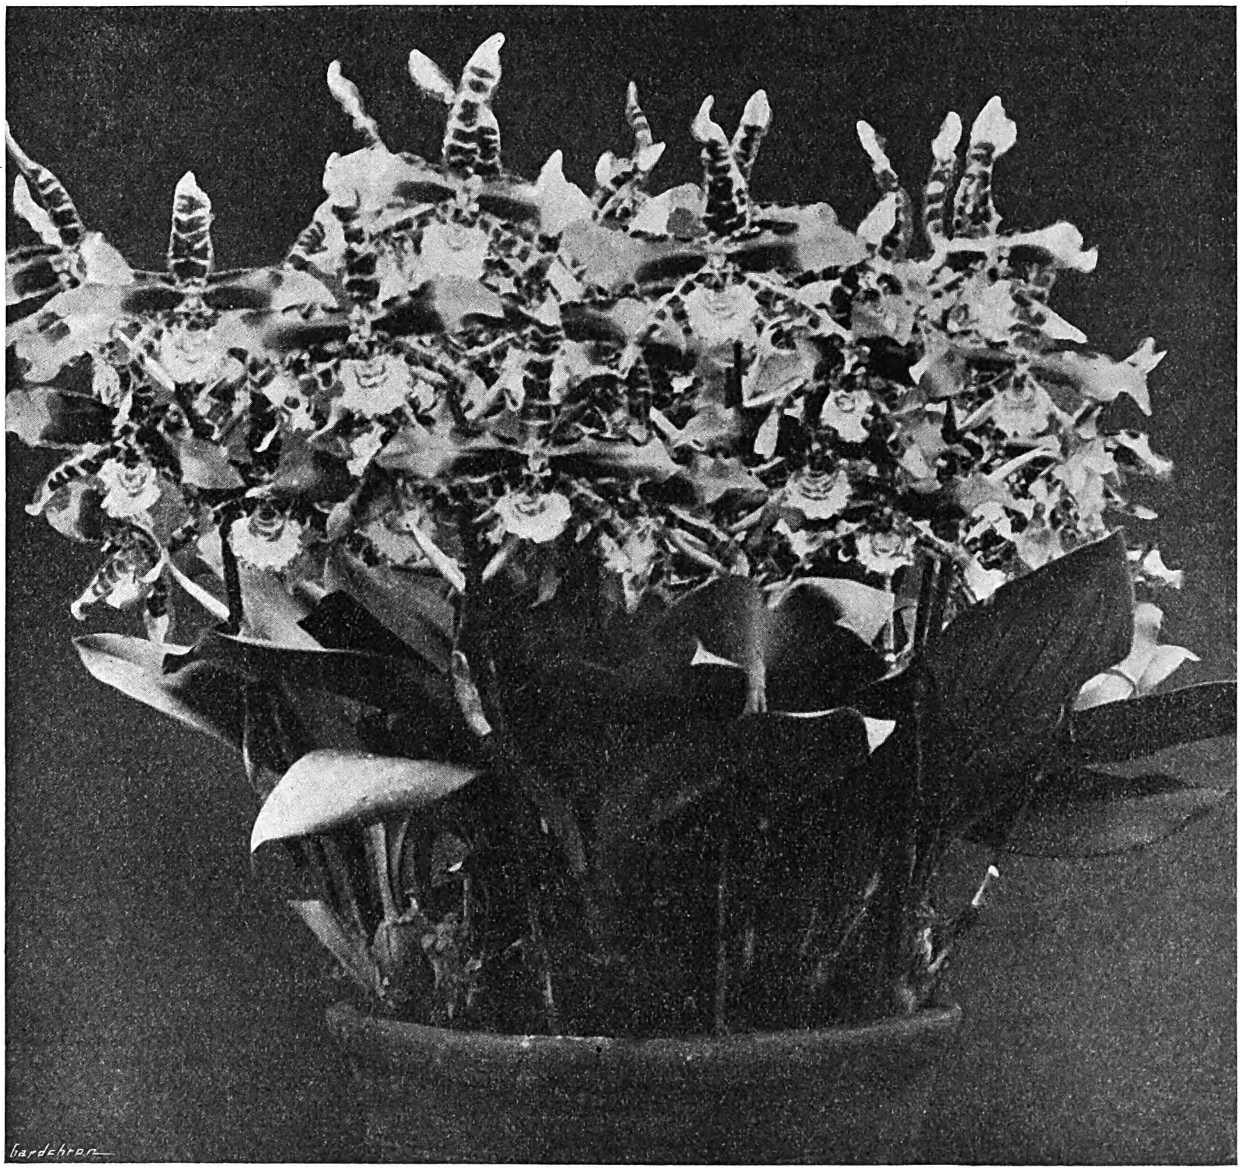


FIG. 230.—A FINE SPECIMEN OF ODONTOGLOSSUM GRANDE.

SOPHRONITIS GRANDIFLORA.

Quite a large number of plants of this small, cool house Orchid may be grown in a limited space suspended from the roof or kept close to the glass of the Odontoglossum house, where they can be shaded from bright sunshine during the spring and summer months. Batches of plants may be subjected to a slightly warmer temperature as the buds begin to show from the partly developed pseudo-bulbs, and by this method, with careful selection of the plants, a brilliant display of flowers may be had from December to April.

The flowers are produced singly on the new growths, therefore this Orchid is most effective when grown in clumps, with several leading points distributed evenly over the surface of the compost. Well-drained, shallow pans are the most suitable receptacles, and the compost should consist of three parts Osmunda fibre, cut moderately fine, and one part Sphagnum-moss; this should be pressed moderately firmly among the roots. Any necessary repotting may be done after the flowering period, when the young roots are seen appearing from the base of the new pseudo-bulbs; if repotting is done during the colder months the plants should be kept at the warm end of the house for several weeks, and care taken in regard to affording water, as with other freshly potted Orchids.

At this season, established plants do not require large quantities of water, although the compost should not be allowed to remain dry for long periods; plants in full growth should be kept just moist at the roots, avoiding extremes either way.

During the dull winter months the bright groups of scarlet flowers of S. grandiflora make an attractive display and should keep in perfection for many weeks if care is taken to avoid moisture collecting on the flowers and young growths; the flowers should also be kept free from contact with the roof-glass. Blooms that open in the spring months should not be exposed to bright sunshine, or the colour may soon fade.

Many distinct and beautifully flowered hybrids have been produced by crossing Sophronitis grandiflora with members of the Cattleya and Laelia groups, and these hybrids are best grown with, and afforded the same treatment as, Cattleyas. Many of the hybrids are considered rather difficult subjects to grow and often show preference for certain positions in the house, where, if they are found to be thriving successfully, it is best to let them remain, as it is often a question of finding the right spot in which to grow some of the less amenable kinds. Scale insects often attack the plants and multiply quickly under the outer skin of the old pseudo-bulbs. The skin may be safely removed from the older ones in order to dislodge the pests, but great care is necessary when cleaning the new or leading growths, as any removal of the outer skin before the pseudo-bulb is thoroughly ripe will often cause decay to get in. *W. Gilden.*

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Masdevallia tovarensis.—This chaste and free-flowering Masdevallia is extremely valuable owing to it being in flower during the dull months of the year. The charming white flowers keep in perfection many weeks if the plants are kept at the warm end of the cool house or, in cold districts, in the intermediate house. Take care to prevent saturation of the compost and to prevent moisture collecting on the flowers, as the latter often causes unsightly spotting. As the plants pass out of flower the old scapes that were retained last year should be removed, some of the current year's scapes being retained if it is desired to produce another crop of flowers next season in conjunction with the new flower scapes. The expanded flowers of this species should not be fumigated or they will be spoiled.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Planting Peach Trees.—Where the planting of young Peach trees is contemplated, the borders should have been prepared early, so that the soil may have time to settle before planting. Good drainage is absolutely essential, but the borders need not be more than eighteen inches in depth. The compost may consist of one part each of good garden soil and turfy loam, with bonfire ash, broken brickbats, chalk or lime rubble to form another part, and the whole thoroughly mixed. The border should be made extra firm to induce hard, short-jointed growth from the start. Prune all damaged roots and shorten those that are too long. Spread out the roots carefully at varying depths, working in among them some of the finer soil, and making the whole quite firm as the work proceeds. Allow a few weeks to elapse after planting before attempting to do any tying.

Pests.—A few pests are causing considerable anxiety to gardeners at the moment, and the most persistent and harmful of these is the capsid bug (Plesiocoris rugicollis), the Apple capsid, which causes a considerable amount of malformation and brown scabbing. The injury is done when the Apples are very small, hindering the development of the fruits and rendering them quite unsaleable. The eggs of this insect which are laid in July, are deeply embedded in the bark on the shoots, and there they remain until the following spring. When they hatch out they are wingless and immediately enter the developing buds, where they puncture the leaves and suck the sap. Later, they attack the young fruits, causing the distortion described. Various washes have been tried with only partial success; but great hopes are entertained of the Long Ashton wash.

Sprayers.—It is essential that the spraying machines and hose pipes should be overhauled to see that they are in working order. During inclement weather the opportunity should be taken to have these machines filled with soapy water and then pumped dry to ensure that "chippings" from internal parts have been washed out. Hose pipes should be tested for leakages and repairs made. It is sound economy to procure the very best hose, as inferior hose means delays and loss of valuable material by bursts.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Clivias.—Where Clivias are grown in quantity a few plants may be placed in a warm house and afforded more water at the roots. Clivias may be had in flower over a long season by introducing successional batches at intervals into warmth. The plants that comprise the main batch should be kept somewhat dry at the roots, but at the same time they should not be allowed to dry out completely. Any insect pests which appear should receive instant attention. Mealy bug is very partial to Clivias.

Bulbs.—Care should be taken to remove any bulbs which are plunged under ashes or other material out-of-doors directly they have started into growth and their receptacles are well filled with roots. It is best to remove them to frost-proof frames when this condition is reached, shading them for a week or so, and then gradually exposing them to sunlight and air. Hyacinths in a forward state may be moved into gentle warmth and given liquid manure. Narcissi, if well rooted, may be gently forced into flower.

General Remarks.—Continue the propagation of Carnations as young growths become available. Cuttings of these should root much better during the next two months than at a later date, and will provide excellent plants for next autumn and winter flowering. Large-flowered and early Decorative Chrysanthemums also need to be propagated now, but cuttings of late Decorative sorts, that are to provide the late batch of plants, should not be inserted for at least another month. Estimate so nearly as possible the requirements of the establishment with regards to forcing shrubs and bulbs, and arrange for batches to be introduced into gentle heat to provide a succession. The chief shrubs employed for this purpose include Azalea indica, A. mollis, Magnolias, Deutzia gracilis, Wistarias, Laburnums and Rhododendrons, but, of course, there are many other suitable subjects. Tulips, Narcissi, Hyacinths and Freesias are most commonly employed among bulbous subjects. Greatest success results from bringing these plants into flower by a gradual process; only introduce them to brisk heat when growth is well-advanced. Many early Peach houses and Vineries will be closed by this date, and the gradual raising of temperatures in these houses should favour good sturdy growth on flowering shrubs.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Pot Vines.—If these were started as suggested at the beginning of this month with a moist, steady bottom-heat, growth should now be well advanced and the vines should soon be coming into flower. As this stage is reached the fermenting material may be renovated, not only to aid and soften fire-heat, but also to maintain root action, a most important factor in securing a good set at this early season. So soon as the inflorescences appear the temperature may be gradually raised to 60°, with a further rise when the flowers open to 65° at night and 75° by day, rising a few degrees higher through sun heat. Atmospheric moisture, on the other hand, should be reduced slightly, and advantage taken of the maximum temperature for fertilising the flowers, cross fertilisation being advisable. From this stage forward rich top-dressing and generous feeding plays a very important part in bringing the Grapes to maturity. In the management of the rods and laterals, it is important to have a full spread of healthy foliage; all shoots should be stopped at the first joint beyond the bunch, and if any space is left the leading laterals should be tied down and in due course stopped; minor laterals may be pinched and regulated in the usual manner.

General Work.—Push forward the pruning, cleansing and top-dressing in all fruit houses. Select sufficient vine eyes for securing stock if any planting of new vines is contemplated, to be potted next month and rooted in steady bottom-heat. All root-lifting and the renovation of borders should be concluded if possible before the end of the year.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Parsley.—Young Parsley in frames should receive close attention. The frames should be ventilated freely so as to prevent damping of the leaves, and any dying foliage should be removed.

Perpetual Spinach.—Hoe between the lines of Spinach when the soil is in suitable condition, as this should be of benefit after so much torrential rain, which has made the surface of the soil hard, thus preventing air penetrating to the roots. A Buco cultivator is a splendid implement for this operation, especially if the bed is fairly large. Early Cabbage beds may be treated in the same way.

Lifting Crops, etc.—Late-sown Turnips which are at present in the ground may be lifted and stored, and the ground dug. If left in the ground, soil should be drawn up around the roots. Jerusalem Artichokes may also be lifted and the tubers placed in sand or fine ashes, care being taken to remove all the tubers from the ground, as if any are left they may prove troublesome to future crops. All trenching and digging should be hurried along so that the soil may derive the full benefit from exposure to the weather, although it is not advisable to work the ground while it is in a saturated condition.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Out-door Peaches.—The pruning and rearranging of the growths of Peaches on walls should be carried out soon. Very little, if any, pruning should be necessary if the fruited wood was removed after the crop was gathered. Some prefer to leave the shoots hanging free of the wall until spring to retard the opening of the flowers, but I have never found this of any advantage. Where properly ripened, as they are this year, no shortening of the young growths should take place, whatever their length, but if cutting back is necessary owing to unripe wood, prune to a growth bud, generally to be found between two flower buds. All ties should be loose enough to allow ample room for the swelling of the shoots next season, or much harm may result, and each shoot should be secured just behind the leading bud to prevent breakage when growth takes place.

General Work.—All fallen leaves should be collected and stacked, if not already attended to, and if Oak and Beech leaves are plentiful these should, if possible, be kept separate. A fairly dry place should be chosen for the leaf heap, for if too damp, decay will be too rapid, to the detriment of the product. All stakes should be inspected during bad weather, and put in order for use next year, after which they may be tied into bundles and stacked. Any damaged mowing machines should be repaired and the cutting blades sharpened if necessary. Glass structures, having been cleared of Chrysanthemums, should receive a thorough cleansing, any brick walls being given a coating of lime or cement wash containing a goodly quantity of paraffin oil. Although Irish lime is often used for this purpose, I do not approve of it, as it throws back the sun-heat and, I am convinced, encourages red spider. Cement wash, on the other hand, absorbs much of the sun's heat during the day and remains clean for a longer period.

Winter-flowering Carnations.—Cuttings inserted at the beginning of the month should now be rooted and must be potted without delay, as there is no nourishment in sand. The smallest possible pots should be used, and a compost of good sound loam, with a little lime-rubble, burnt soil and sand added. Wash off any sand adhering to the roots, and after potting, keep the plants close for a few days, a light spray being in most cases all the watering necessary for some time.

THE DAVIDIAS.

No introduction of recent years has caused so much interest among cultivators of trees as the Chinese Dove Tree. Most authorities concerned define two distinct species, Davidia involucrata and D. Vilmoriniana.

Seen growing together in gardens the two are easily identified. D. involucrata has very marked red colouring on the young shoots and petioles, and the undersides of the leaves are conspicuously downy. Moreover, it is not such a free-growing, nor so hardy a tree, as D. Vilmoriniana, and so far as I am aware has not yet flowered under cultivation in this country. D. Vilmoriniana is much more free in growth, while the undersides of the leaves are quite devoid of down, and glaucous. Many of the trees planted in various parts of the country and raised from seeds collected by Mr. E. H. Wilson during his first expedition to China for Messrs. James Veitch and Sons, from 1899 to 1901, now flower annually and produce fruits.

Davidia involucrata was first discovered in Mupin, western Szechuan, and specimens were collected by the Abbé David in 1869. The first trees introduced to our gardens were raised from seeds collected by Mr. Wilson during his second expedition during 1903-1904.

D. Vilmoriniana was first discovered in Wushan Hsien, eastern Szechuan, by Professor Augustine Henry, in 1888. It was later found, and seeds were collected, in north-eastern Szechuan by Père Farges, in 1897. Of the thirty-seven seeds sent by him to the late M. Maurice de Vilmorin, only one plant was raised, this germinating in 1899. From this plant cuttings were rooted, one of which was sent to Kew and another to the Arnold Arboretum. The species first flowered at Les Barrés in 1906. The plant received at Kew from M. Vilmorin in 1901 was planted in the Himalayan House and flowered for the first time in 1913. It was illustrated under the name of Davidia involucrata in *The Gardeners' Chronicle* of July 13, 1918, (Vol. LVIII, p. 43, Fig. 14), and as depicted, shows more flowers than leaves. As one would expect from such a free-growing tree, it quickly attained a height of thirty feet and outgrew its position in the centre of the Himalayan House. With considerable difficulty the tree was moved to the main Temperate House, but failed to survive the shift. Fortunately, it had produced fruits and several seedlings are now growing at Kew.

The tree of D. Vilmoriniana illustrated (Fig. 231) is one of some thirteen thousand seedlings raised from seeds collected during November, 1900, by Mr. Wilson in the woods south of Ichang, western Hupeh. It is twenty-seven feet six inches in height, and has a girth near the base of twenty-eight-and-a-half inches. The beautiful picture this tree produces when in flower may be judged from the statement that it recently brought to maturity some four hundred fruits.

One of the largest trees in the country is apparently a specimen growing at Buckhold, Pangbourne, Berkshire. It is forty-two feet in height with a stem girth near the ground of thirty-nine inches, the branches having a spread of about forty feet.

From the seeds collected in 1900 by Mr. Wilson, the first tree to flower was one at the Coombe Wood nursery, in May, 1911.

In a wild state, D. Vilmoriniana attains a height of about sixty feet. The leaves in their general appearance suggest those of a Lime (Tilia). The inflorescences are borne during the second half of May, and when freely produced make a remarkably attractive spectacle, suggesting dozens of ladies' small white handkerchiefs waving in the breeze, or, at a distance, as the American name of Dove Tree suggests, looking like flocks of doves among the newly developed leaves.

The attractive portion of the inflorescence consists of two large bracts of unequal size enveloping the true flower. When fully developed these are pure white, the larger one some six inches long and three inches wide, the smaller bract less than half these dimensions. The essential parts of the flower are produced in a hemispherical cluster of numerous stamens and an ovary which later develops into a sub-globose fruit containing the hard, corrugated nut.

Seeds, layers and cuttings provide means of increase.

Presumably because they had been kept dry for some time before sowing, the seeds originally imported took two years to germinate. It is found, however, at Kew, that if the fleshy portion of the fruit is removed so soon as mature and the fruits are sown at once, a goodly proportion of the seeds germinate the following spring and the seedlings attain a height of twelve to eighteen inches during the first year of growth.

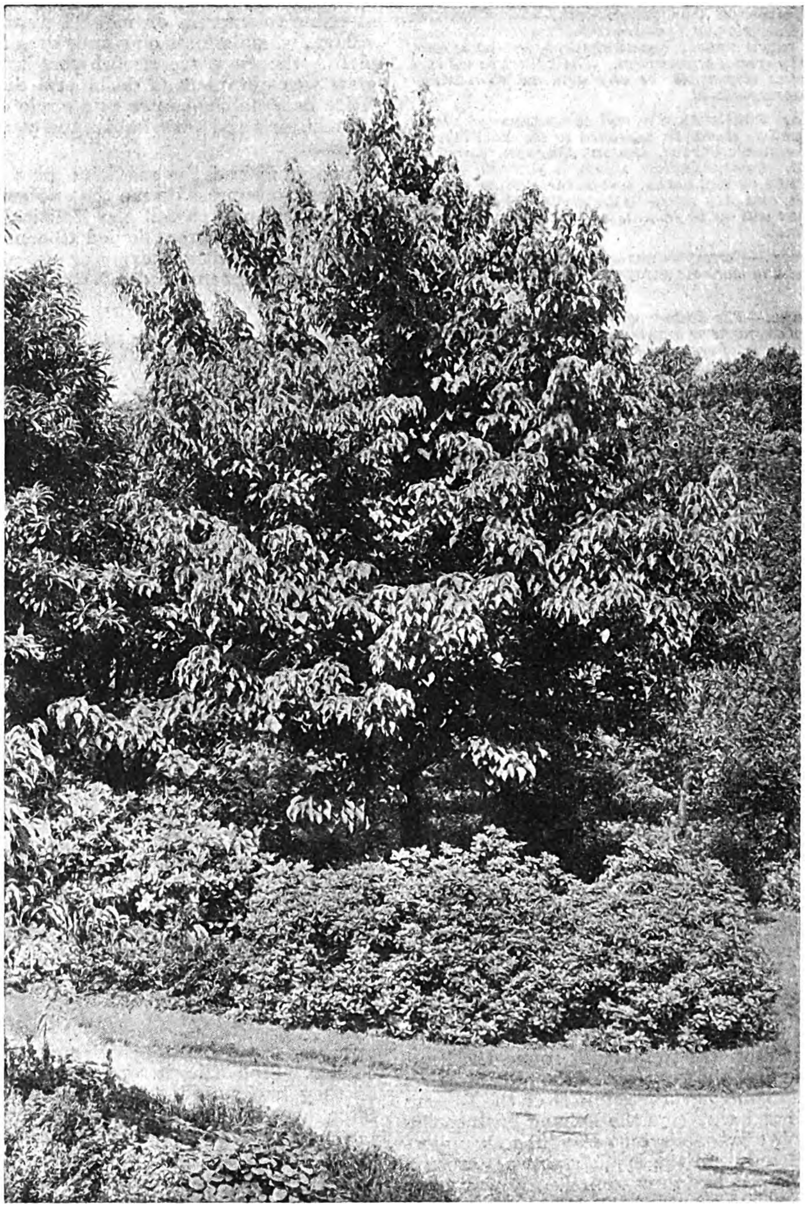

FIG. 231.—DAVIDIA VILMORINIANA AT KEW.

Where the conditions are available, place the nuts in the fibre of a propagating case, with slight bottom heat. Failing this, sow the seeds in shallow boxes of very sandy soil in a greenhouse, cold frame, or outside. It is very noticeable that uncleaned seeds take longer to germinate than cleaned ones.

The best means of rooting cuttings is to insert portions of the half-ripened growths in a close propagating case, with slight bottom heat, towards the end of July. A record of experiments made in the rooting of cuttings of D. Vilmoriniana appeared in the issue of *Gard. Chron.* of March 23, 1929, p. 227.

The Davidias thrive under the average conditions we afford ornamental trees in the pleasure grounds, parks and open woodland. They should be given a good start in deeply trenched, loamy soil.

Avoid planting, if possible, in wind-swept positions, as in a mild spring new growth starts early, and cold, cutting winds, or late spring frosts, may injure the young and tender leaves.

During one unusually early spring the half developed flowers on the Davidia tree illustrated were badly damaged by frosts during the first week in May.

A third species of Davidia, D. laeta, was described by M. L. A. Dode, the French botanist, in the *Revue Horticole* in 1908, but his character of a glabrous leaf, yellowish-green beneath, is not constant, and under cultivation it is indistinguishable from D. Vilmoriniana, and it is now not generally regarded as a valid species. In *Plantae Wilsonae*, Mr. Wilson considers it a question of position—whether the tree is growing in shade or fully exposed. *A. Osborn.*

[Until quite recently, considerable confusion existed as to the exact status of D. Vilmoriniana, this having been regarded as a form of D. involucrata, with the result that the various records under the latter name have, apparently, referred to D. Vilmoriniana.—Eds.]

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London: or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XL.—From the Dibang to the Dihang.

A PHYSICAL map of this part of the Indian Empire shows the long, flat, green trough of the Assam valley, with the Brahmaputra forming a meshwork composed of ever-shifting channels and chapri (islands), in the middle flowing westwards, and the brown highlands (brown on the map, that is) clasping it closely—the Himalayas to the north, the Naga and Khasia hills to the south. At the head of the trough the rivers break through the girdle separately, rushing down from the cold, snow-bound ranges to the north; first and foremost the famous, mysterious Dihang, in the centre the small Dibang (Fig. 233), and further east the Lohit. These three, with other smaller rivers, join at Kobo, situated at the extreme apex of the trough, to form the Brahmaputra. My object now was to go right round the head of the trough at the very foot of the hills, starting from Sadiya and working round from the Dibang to the Dihang and from the Dihang back to the Lohit, with excursions into the hills as opportunity offered. In the last chapter we crossed the Dibang; I had now to make my way from Dambuk to Pasighat, through the Abor foot-hills.

On December 3, we started again, the Dambuk coolies taking us so far as the Sisseri river, reached in two hours. The river bed is fully six hundred yards wide, but at this season it was nearly all shingle and sand banks; nevertheless, we had to ford the river waist deep, and the water was bitterly cold. There were several fish traps here—long, funnel-shaped baskets dragging in the swift current by Bamboo ropes attached to a spar.

The Dambuk coolies took me across the Sisseri, dumped me on a sandbank and fled. Half-an-hour later the Sipo contingent arrived to take me on to their village, where we arrived in the afternoon; here we camped in the bed of a stream.

It may be remarked that all the hill tribes have a sound empirical knowledge of the dangers of infectious disease, and understand quarantine. When an epidemic breaks out they at once isolate the village. The village itself takes all reasonable precautions, and either barricades the path with tree trunks, or puts up some sign, such as a pair of crossed sticks, so that anyone infringing the taboo does so at his own risk. However, it appeared that there was no epidemic at Sipo—the story had been fabricated by Dambuk; at least, so the Sipo Abors were at pains to impress on me. I went up to the village, which stands on a spur over-looking the plain, whence a wonderful post impressionist view was obtained at dusk, and drank apong (Rice beer) in the centre of a circle of men and women, girls and boys, babies and pigs, fowls and mithan.

The Gam and the medicine man were most anxious to impress on me that no one was sick, and begged me to tell the Political Officer in Sadiya that they were denied all communication with Dambuk without cause or just impediment. The only symptoms of death and disease became apparent next morning, when I could get no coolies. Sipo said it was not their business, as they had supplied them the previous day. Silik, another village not far off, said they had not any coolies. The fact is, none of the hill tribes really like doing coolie work, especially at this season when all the girls are at work in the fields, and all the young bucks out hunting in the jungle with bow and arrow. The Political Officer, when he wants coolies, has merely to demand that so many shall be ready at the specified time and place; if they are not there unpleasant things happen. But although I was travelling with all the authority of a government officer, I had no escort, and no way of enforcing my demands. However, the Sipo Gam did his best for me, although it was well past midday before he beat up eight harassed coolies, and we got off. Luckily, the next village on the line of march was only about five miles away, and we camped at dusk after a dull walk through secondary growth and new clearings. The huge feathery grass—a species of Saccharum—was conspicuous here, and I picked up the twisted pods, full of hard, scarlet seeds, of some Leguminous tree or liana—possibly a Pithecolobium.

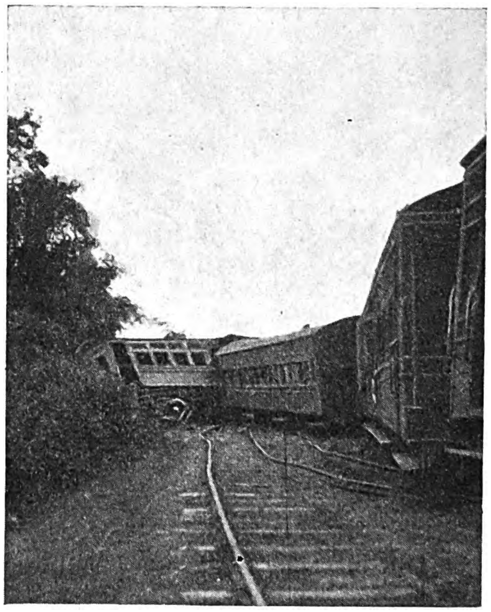

FIG. 232.—THE DERAILED ASSAM MAIL.

The Mebu Abors were friendly and efficient, and produced eight coolies early the following morning. A monotonous march of six miles through the jungle brought us at midday to the bank of the Dihang; and we passed abruptly out of the cool, moist twilight into the slashing glare of the open river bed. Crossing several hundred yards of pebbles, we reached the river opposite Pasighat, and were ferried over by dugout.

It was a gorgeous day, and the view of the Dihang, backed by the thickly-forested mountains, with Pasighat sitting tidily at their foot, was very fine; I looked forward to several pleasant days here, with excursions into the jungle. However, no sooner was I settled in the bungalow than I received a cable forwarded several days previously from Sadiya, which made a quick move to Calcutta essential; and the only plant I collected in Pasighat was a Strobilanthes with large, violet flowers. I was in a fix. There was not a single sahib in Pasighat at the moment, and without a car it would take me at least two days to reach Sadiya, even if boats or carts had been ready on the spot—which they were not.

However, a few miles away a man I knew very well who was working with a timber firm, had his camp, and I sent him a note. He came in to dinner that night, and promised to drive me through to Sadiya next day, December 6. The actual distance in an air line is about thirty miles, but there are no air liners in Assam yet, and the route is as follows:—(1) Pasighat to Kobo, twenty-three miles by road; (2) cross the Brahmaputra to Rongdoi, say, one mile; but it takes two hours with a car, the current being very swift and the raft (Fig. 234) unwieldly; (3) Rongdoi to Saikhoa Ghat up the left bank of the Lohit, thirteen miles by road; and on another two miles to the ferry; (4) cross the Lohit—this does not take long, even with a car; (5) from the ferry to Sadiya, three miles by road. Thus it took us six hours, for on the dirt roads of the frontier tract one cannot average more than about fifteen miles an hour—at least, with a four-cylinder car.

Two days later, I left Sadiya for Calcutta; crossing the shrunken Lohit by motor-launch, we stuck on a sandbank, and I missed my train, and had to spend the night at Saikhoa, since there is only one train every twenty-four hours. Next morning I went for a walk down the Assam Valley Trunk Road—only a dirt road for all its grand manner—which goes to Gauhati, 335 miles away; and noticed a number of flowering shrubs, among them quite a pretty Hibiscus with salmony-pink flowers. There is another Hibiscus commonly seen in the foot-hills among secondary growth, with big, bright yellow flowers like floppy Poppies. Another bushy shrub in flower was a sort of Bladder Senna with yellow flowers darkening to a warm brown as they aged. There was also a 'cucumbersome' creeper with palmate leaves and small, cream-coloured flowers followed by tiny, warty-looking Cucumbers. But most of the area around Saikhoa is cultivated, and the trees and shrubs along the roadside were covered with dust.

That afternoon I caught my train. After coming safely through all the perils and tribulations of the Mishmi and Abor Hills, it was rather unkind of the Assam mail to choose that particular day (that is to say, the next day, December 11) to wreck itself (Fig. 232), and that without visible cause. During the monsoon, bridges are often washed away, or sections of the line sag out of sight, on the Bengal Assam Railway; and even during the cold weather it sometimes happens that the engine hits a careless elephant and bounces into the jungle, or richochets off a stray buffalo. But to be piled up in the dry weather, without hitting anything, on a sound track, and that in the darkness and mist of early morning, is unfair. Two waggons, two passenger coaches, and the dining car were smashed and hurled into the jungle on either side of the impermanent way. The next coach, in which were the European passengers, most of us asleep, having lurched off the rails and run on for a hundred yards, was about to telescope itself on the shambles ahead, when the whole outfit came to a standstill; the couplings had broken in front some time previously and the engine had gone on alone. So we got off lightly; but it was all very annoying, as we were twenty-four hours late in Calcutta.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 22, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24; September 7, 16, 28; October 12, 26; November 9, 23, 30; December 7, 14 and 21, 1929.

We heard afterwards that the engine driver was asleep when the accident happened; that the accident was caused by the breaking of an axle-box, whereby some wheels left the rails; and that we ran on gaily over the sleepers and the ballast for two miles, safely negotiating a narrow bridge over a deep river, before the whole train got the jumps and piled itself up. Needless to say, only those of us who were in the train knew what a narrow escape we had had; for no one having been killed, and only a few natives injured, and the wreck being safely entombed in the jungle a hundred miles from anywhere, the railway company casually issued a notice to the Calcutta press that "owing to the derailment of five coaches of the Assam mail, passengers and mails would be trans-shipped," etc., etc., and the company did not even indemnify us for broken time!

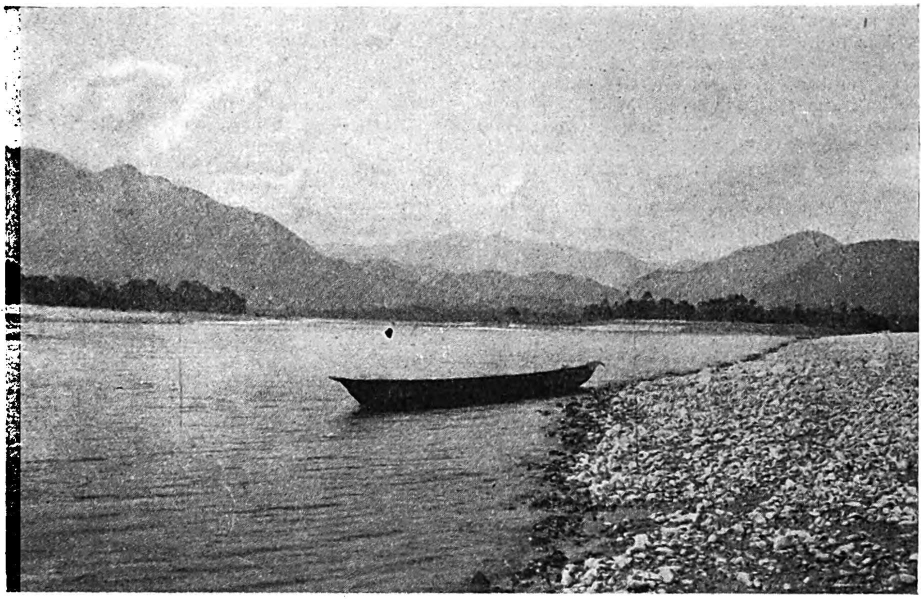

FIG. 233.—THE DIBANG AT NIZAMGHAT.

However, I just caught the Roosevelts before they left Calcutta for China, and arranged to join them in Cambodia in the spring, and within four days of seeing them off to Rangoon, I was speeding across India to catch my boat at Bombay. *F. Kingdon Ward.*

The End.

THREE NEW RHODODENDRONS FROM TIBET.

In going over my 1924, 1926, and 1928 collections of Rhododendrons with Mr. J. Hutchinson, at Kew, we came across the three described below, and being unable to match them, named them as new. In my field book I found full descriptions, written in Tibet in 1924 from living plants; so evidently I suspected them of being new even then.

No complete list of these Rhododendrons has yet been published, although it is hoped to have one ready soon. The apparent delay is not really so surprising when it is remembered that the three collections together contain nearly 350 numbers, with over 150 species, of which, perhaps, twenty per cent. are distinct new species, excluding varieties.

Professor W. Wright Smith and Mr. H. F. Tagg have kindly undertaken most of the elepidote species at Edinburgh. Mr. J. Hutchinson and myself have been engaged on the lepidote species at Kew; but owing to Mr. Hutchinson's recent absence in Africa and to his other labours, and to my own various absences in Asia, the work has been held up. From time to time descriptions of new species have been published by Mr. Tagg in the Edinburgh *Notes*, and in *The Gardeners' Chronicle*, either from the herbarium specimens, or, when these lacked flowers, from cultivated plants as they came into flower either in the botanic gardens or in private gardens and were forwarded to Edinburgh by growers for identification; and it may be some time yet before a full determination is possible, as there are several species whose identity cannot be satisfactorily settled until they flower in this country. In the meantime, following this precedent, I am publishing the names and descriptions of three new species, which are likely to flower in 1930.

Considering the number of Rhododendrons known from this part of the world, and the numerous names which have recently had to be reduced as a result of a livelier appreciation of the variation of species, twenty per cent. of new species may seem rather a tall order. But when we remember that all three expeditions were made, not merely into unexplored country, but into the almost inaccessible heart of the mountains which hitherto have been attacked only from their ends, from Sikkim in the west and from Yunnan in the east, the proportion is not unreasonable.

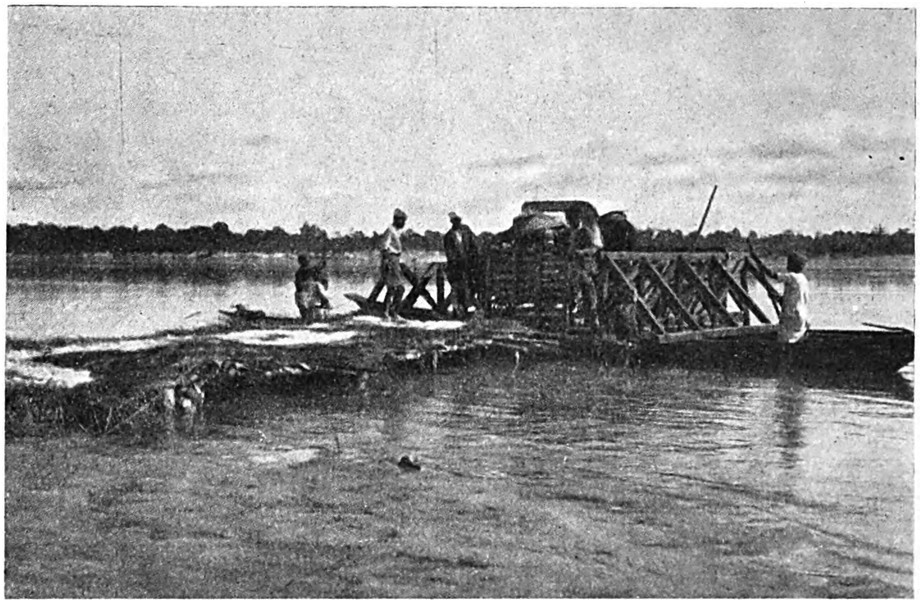

FIG. 234.—THE FERRY CROSSING THE BRAHMAPUTRA.

Rhododendron rivulare, Ward.

An aromatic, spreading undershrub a foot high. One-year-old twigs yellow, covered with orange, scurfy scales; bark ultimately grey.

Young leaves with closely lepidote upper surface, scales silvery; under surface densely lepidote, the scales at first silver, eventually turning buff; margin with a few long, silken hairs, which are soon lost.

Adult leaves shortly petiolate, oval, 0·75 inch long, 0·5 inch wide, apex with a ruby-red mucro. Upper surface glistening, covered with silvery scales; lower surface densely lepidote, fawn-coloured; petiole 0·06 inch long, with chaffy scales which extend to the midrib.

Inflorescence a terminal umbel of two to four flowers. Pedicel 0·6 inch long, red, lepidote. Calyx red, leafy, cut to the base; lobes oval or obovate, 0·25 inch long, margin finely ciliate, the under surface lepidote at the base, scales yellowish.

Corolla rose-purple, with darker spots on the upper lobe, slightly oblique, butterfly-shaped, flattened, with very short tube, the lobes rounded, lepidote on the reverse; one inch long, 1·5 inch wide; glabrous inside except for a slight puberulousness at the throat.

Stamens ten, sub-equal, spreading, each filament with a dense tuft of silken, white hairs at the base.

Gynoecium one inch long. Ovary conical, lepidote, slightly fluted. Style red, 0·8 inch long. Stigma discoid, lobulate.

The following field note is attached to the type:—"Dwarf shrub, forming little bushes about a foot high, in open pastures and along the banks of the stream, often overhanging the water. Flowers bright rosy-purple with darker spots on the upper lobe." Doshong La, southern Tibet, lat. 29° 30′ N., longt. 95° 0′ E., 10,000 to 11,000 feet. 23.6.1924. Kingdon Ward, 5,828. Type in Herb. Kew.

It is also found north of the Tsangpo. "Flowers over, fruits ripening, Calyx red. Undershrub of six to twelve inches, in open. boggy meadows, forming clumps." Nambu La, southern Tibet, lat. 30° 0′ N., longt. 94° 30′ E., 12,000 to 13,000 feet. 13.8.1924. Kingdon Ward, 6,087. Also No. 6,224 (fruit), from the Doshong La.

The next record of this species is from far northern Burma:—"Flowers vivid purple with darker spots on the upper lobes. Undershrub of a foot or less to eighteen inches, growing in thickets with other species, nestling down amongst them (*c.f.* No. 5828 collected in Tibet in 1924). . . . The first of three local species to flower. [The other two being R. saluenense, Franch., and R. calciphila, Hutchinson et Ward]. Practically over by the time the other two are in bloom." Seinghku Wang, Burma, lat. 28° 8′ N., longt. 97° 24′ E. 11,000 to 12,000 feet. 12.6.1926. Kingdon Ward, 6,903.

"Dwarfed alpine growing on the slate screes; now in full bloom. Grows also with the Lapponicum Rhododendrons on the open moorland slopes at 14,000 to 15,000 feet." Same locality, 14,000 feet. 7.7.1926. Kingdon Ward 7,061. Also No. 7,062. "A later-flowering variety of No. 6,903." Also No. 7,553. "Autumn-flowering of No. 6,903. The young foliage is strongly aromatic."

A third record is from Assam:—"A dwarf aromatic undershrub crowded with bright purple flowers. Grows socially in the alpine region." Mishmi Hills, Assam, lat. 28° 15′ N., longt. 97° 0′ E. 11,000 to 12,000 feet. Kingdon Ward, 8,229.

R. rivulare, seen growing by itself, at once recalls R. calostrotum, although when both species are compared the differences are at once obvious. The calyx of R. rivulare is almost glabrous instead of densely crusted with scales, and the margin only minutely ciliate. It has much shorter pedicels, giving a more compact truss which consists of from two to four flowers, instead of two only as in R. calostrotum. Lastly the scales of the under-leaf surface are buff, not cochineal-red.

R. rivulare is a much more gregarious species than R. calostrotum, or, indeed, than almost any other 'Saluenense' species; it forms wide drifts by itself, in this respect resembling the 'Lapponicum' type. Most of the 'Saluenense' Rhododendrons, including R. saluenense, occur either scattered through dense underscrub composed of several species, or the plants themselves are scattered over the turf slopes and on rock outcrops, among dwarf Bamboo, like R. keleticum.

The species has a considerable extension from southern Tibet to northern Burma on a line running N.W.-S.E. for two hundred miles. R. calostrotum has only been recorded from the Hpimaw district of north-east Burma, 150 miles south-east of the Burma record for R. rivulare.

The specific name, of course, refers to the original locality, where the plant overhung the stream.

As regards the horticultural outlook, R. rivulare should prove at least as hardy as R. calostrotum, and being more heavily flower-powered, is really the better plant.

RHODODENDRON FRAGARIFLORUM, Ward.

Undershrub with ascending stems rising to a height of four inches above the ground and forming dense, much-branched tuffets. Bark ash-grey. Young shoots slightly lepidote; juvenile leaves with both surfaces lepidote, margin reddened, with a few scattered hairs, and prominent red mucro; aromatic.

Mature leaves oblong-oval, 0·5 inch long, 0·25 inch wide, margin slightly inrolled, mucro more or less sunk, inconspicuous; upper surface dark green, with closely-set, glistening scales, lower surface paler, shiny, with widely scattered, small, bronze-coloured scales.

Flowers in terminal umbels of two, three or four. Pedicels 0·4 inch long, lepidote, red. Calyx large, five-lobed, densely lepidote at the base, the scales extending to the backs of the lobes; cut to the base, the lobes oval, red, the margin finely waved, beaded with small, glistening scales.

Corolla five-lobed, flattened, slightly irregular, about one inch wide, 0·5 inch in depth, purple, or crushed-Strawberry colour; tube very short, lobes oval or oval acute, 0·5 inch long, 0·3 inch wide.

Stamens ten, sub-equal, about 0·5 inch long; filaments glabrous, except for a tuft of crimson hairs at the base, more developed in the upper five than in the lower five; purple.

Ovary conical, truncate, 0·1 inch long, green, densely lepidote, with five shallow grooves. Style 0·5 inch long, glabrous, crimson, with discoid lobulate stigma.

"Forms hassocks and continuous carpets not above six inches high on the exposed side of the pass. Leaves strongly aromatic. Flowers in small trusses of two, three or four. In bud." Temo La, southern Tibet, lat. 29° 35′ N., longt. 94° 35′ E., 15,000 feet. 5.6.1924. Kingdon Ward, 5,734.

"Flowers the colour of crushed-Strawberry, slightly fragrant. All over the open alpine region. Flowers from mid-June to mid-July or later." Nyima La, southern Tibet, 14,000 to 15,000 feet. 20.6.1924. Kingdon Ward, 5,810. Type in Herb. Kew.

This is the 'Strawberry Saluenense,' which name has been preserved. In several respects this species departs from the usual 'Saluenense' type, particularly in its foliage, the scales on the under leaf surface being very small and wide apart. Flower stalks very short; margin of calyx not ciliate. The flower colour is probably unique in the genus. R. fragariflorum occurs on both sides of the Tsangpo, but is much more common on the northern (dry) ranges than it is on the southern. On the Temo La it grows gregariously with two other species, a 'Lapponcum' and a 'Cephalanthum.' It is an extremely bright and floriferous plant, the contrast between the dark olive-green leaves and the crushed-Strawberry flowers being most striking. It seems to form a link between the 'Saluenense' and the "Lapponicum" series, and is quite unlike any other dwarf Rhododendron.

RHODODENDRON TSANGPOENSE, Ward.

Aromatic, bushy undershrub, one foot to two feet high. One and two-year-old shoots with scattered scales. Bark ultimately grey.

Leaves aromatic, oval, with mucronate apex, 1·1 inch long, 0·5 inch wide; upper surface mat, dark green, lower covered with a waxy, bluish-grey bloom, both surfaces lepidote, with scattered scales. Petiole 0·1 inch long, upper surface grooved.

Inflorescence a loose terminal umbel of four to five pale purplish-pink flowers. Pedicel one inch long, reddened on one side, lepidote. Calyx regular, campanulate, 0·3 inch long, cut almost to the very lepidote base; lobes oval, green, with scattered scales which likewise bead the margin.

Corolla campanulate, 0·75 inch long, 1·25 inch wide, five-lobed, the lobes oval, spreading, 0·5 inch long; puberulous inside at the base.

Stamens ten, alternately longer and shorter; the longer 0·6 inch, the shorter 0·4 inch long: filaments expanded at the base, pubescent right up to the anthers.

Ovary cylindric, fluted, lepidote, green; 0·1 inch long. Style glabrous, fleshy, red, bent, rather at right angles near the base; expanded into a cup at the summit, containing the five-lobed stigma.

"Grows as dense scrub one to two feet high on steep alpine slopes, on both sheltered and exposed flanks. Style sharply bent down." Doshong La, southern Tibet, lat, 29° 30′ N., longt. 95° 0′ E. 12,000 to 13,000 feet. 24.6.1924. Kingdon Ward, 5,844. Type in Herb. Kew.

[No. 5,844A. appears to be a different species, more closely akin to R. charitostreptum.]

This species was abundant on the range south of the Tsangpo, forming much of the scrub by itself. The clear Apple-blossom-pink flowers are particularly charming, contrasting with the bluish-white under-leaf surface. R. tsangpoense differs from R. glaucum, its closest relative, in having the filaments hairy almost to the top, and a nearly glabrous—not densely scaly—calyx. The leaves have a rounded apex and are very laxly lepidote below. *F. Kingdon Ward.*

ALPINE GARDEN.

ROCK GARDEN VERBENAS.

The statement by *S. A.*, in his note on Verbena chamaedryoides, p. 403, in which he writes:—"This Verbena is probably the hardiest of all the plants of the genus," is not borne out by my experience of several of the Verbenas.

The heliotrope-coloured V. venosa, often employed extensively as a summer bedding plant, sometimes survives the winter, so long as it is not too severe, and grows away again quite well the following year. V. chamaedryoides has also survived the winter with me—only just—but invariably it is so badly crippled through the ordeal that the early summer has arrived before life becomes very apparent in it. This being the case, plants of V. chamaedryoides left to winter out-of-doors, no matter how protected the site may be on the rock garden, are never relied upon for next season's display, a batch of young plants from cuttings being wintered in a cold frame which is covered with mats during severe weather. Incidentally, this Verbena seems to strongly resent dampness in the winter, the growth dying off unless a free circulation of fresh air is maintained in the frame whenever possible.

Another species which is certainly hardier than V. chamaedryoides is V. radicans, which although not possessed of the "fiery" blooms of the former species, is a valuable subject for brightening the rock garden in late summer and early autumn.

V. radicans survived several winters in the open rock garden, with no protection other than a dense bush of the evergreen Berberis buxifolia on the north-east side, and each year made a wide, matted carpet of interlacing growths clothed with glossy, dark green, deeply divided leaves. It should be planted in a warm, sunny position in loamy soil containing a goodly quantity of lime-rubble to render certain its free-flowering. In shady positions it grows and covers the ground in splendid fashion, but flowers in but niggardly manner; but when in a sunny position the carpet of foliage becomes sheeted with heads of small, pale lavender flowers carried on stems six inches high arising from the leaf-axils. Even with V. radicans, however, it is wise to winter some stock plants in frames. Stock is easily secured, as the creeping growths produce roots from the nodes along their whole length, and if these are severed and potted up a more than sufficient stock may be obtained.

I believe also that V. Mahoneti, a species that has received considerable publicity by certain nurserymen during the last two years, is hardier than V. chamaedryoides, and will survive mild winters in the open, although I have not grown this species myself. I may state that no Verbena survived last winter in my rock garden—but then, what self-respecting Verbena would! *Kent.*

ANEMONE NARCISSIFLORA.

The genus Anemone embraces a large number of plants which are of the highest beauty and which have well deserved the devotion of flower-lovers in this and other countries for generations. Yet some of the most beautiful are absent from many good gardens, and their inclusion would be greatly to the gain of all who love the best hardy flowers. Among the numerous species of merit which are not so common as they ought to be is A. narcissiflora, a plant which is rather widely spread in nature, and which varies considerably in some of its characters, yet yields hardly any forms which may be regarded as flowers to be despised. It is very frequent throughout the European Alps and in several parts of Asia and, crossing the Behring Straits, is found in various districts of North America. In every region it is very beautiful. What is generally accepted as the typical plant grows about a foot in height, and is adorned with soft and delightful, fan-shaped leaves and crowned with eight or ten charming flowers of creamy-whiteness, tinged frequently outside with pink and resembling Apple blossom.

The various forms have had specific and varietal titles bestowed upon them. A very delightful one, quite uncommon, is A. n. var. polyanthes, which was introduced simply as A. polyanthes, and which the writer had for many years after receiving it from the late Max Leichtlin, of Baden-Baden. This is a more robust plant than most of the forms, but my plant lacked the pink exterior flushing which is such a fine feature of what I consider the finest forms of A. narcissiflora. This comes from that fruitful field of new plants, Tibet, and extends into Kashmir. A poor form is A. n. var. monantha, which only bears one flower on a stem, and the eastern Asiatic form called A. n. var. demissa is more fluffy and has weaker stems. Farrer describes a Russian form, which I have not seen, as still more fluffy and hairy. This is called Anemone villosissima or A. villosa.

Those who have grown A. narcissiflora for some time are not always prepared to accept Farrer's opinion that its life in our gardens does not exceed six or seven years. I have had plants for a much longer time than that, but Mr. Farrer's statement that plants may damp off is one which suggests care in planting, especially in wet districts, ample drainage being essential and heavy soil to be avoided.

A. narcissiflora is generally easily obtained in pots from nurseries, but it may be raised from seeds, which, however, are sometimes slow of germination.

LYCHNIS LAGASCAE.

IN past days, when the culture of rock plants was not so well understood as now, and when the choice of these was more limited, the Spanish Lychnis Lagascae was looked upon as one of the plants much to be desired, and presenting difficulties in cultivation which required special consideration. These difficulties have largely disappeared, and the fact is that this Lychnis is not among the plants which are in the front rank of alpines, and that it may be left out of any garden without deep regret. It was, and may still be, frequently lost in winter when on the level parts of the rock garden, and it came to be considered that it was only satisfactory when in the chinks of a wall garden or planted in the vertical crevices of the rock garden. In such positions certainly success generally attends the effort, and the writer has seen some good masses of L. Lagascae under such conditions In wet districts and where there is not ample drainage, such treatment is to be advised, but in parts of the country with a moderate winter rainfall, and where the soil is thoroughly drained, there need be little prospect of failure. Still, when one remembers that this Lychnis is found in the crevices in the Spanish cliffs, it is obvious that the wall garden or the chinks of rock work will present the most congenial conditions for its successful growth.

When happy, it forms a small mass of straggling growths, with blue-grey leaves, four or six inches high, and these produce, all the summer through, a number of small, starry flowers of a more or less faint carmine colour. This sounds even more attractive than the reality, for it must be stated that the whole effect is rather disappointing, reminding one of some mediocre annual. It loves a sunny place and, with perfect drainage, it should flourish. It comes easily from seeds, and it may also be propagated by cuttings. I have not seen any variation among seedlings, but this is quite probable and forms of superior habit or colour may be found. *S. Arnott.*

ROSE GARDEN.

ROSE RODHATTE.

I CONSIDER this Rose to be one of the best varieties in the group of dwarf Polyantha Roses suitable for bedding purposes, and it is an ideal variety for furnishing large beds.

It is a strong grower, has splendid green stems and foliage similar to that of the Tea Rose, and the blooms are deep cherry-red in colour, semi-double, and very suitable for cutting. In a large bed of it planted four years ago I have never seen any signs of mildew.

Rodhatte commences to bloom early in June and continues to do so until the end of September, the flowers retaining their colour well; when the bed is in full bloom it is extremely effective and is noticeable from a distance. I think this would be a very valuable variety for massing in public parks.

Edith Cavell, another of the dwarf Polyantha varieties, is a good bedding Rose which is now grown extensively. In foliage and bloom it takes after Crimson Rambler; in fact, it might almost be called a dwarf Crimson Rambler, but it has one fault—it does not keep its colour well.

Another good bedding Rose of this section is Else Poulsen, also grown quite frequently and resembling R. Rose Orleans, but for continuity of blossoming, general effectiveness and freedom of growth there is none which, in my opinion, surpasses R. Rodhatte. *David D. Robertson.*

GARDEN NOTES FROM SUUTH-WEST SCOTLAND.

WOULD that Fatsia japonica, that opulent cousin of our native Ivy, could be induced to flower a month earlier than it does. In southern England it may make its display in October, but in our more northerly latitude November is the month when it should be at its best, well set with great panicles of bloom like carved ivory. It was distressing to see these marred by a few degrees of frost early in the month; but the shrub is well worth a good place, were it only for its noble foliage. I measured one of its great palmate leaves this morning—nineteen inches by seventeen inches; but when Mr. Bean wrote sixteen years ago that Fatsia bears "about the largest leaves of any hardy evergreen," Rhododendron sino-grande had not yet revealed its dimensions to British gardeners. The leaves of that species are sometimes three feet long; but perhaps it may not be accounted hardy in all parts of our island.

Billardiera longiflora deserves to be far more generally known and grown than it has been hitherto. As a native of Tasmania, it may be reckoned of doubtful hardiness, except in the milder parts of our island; but in my experience it never flinches from frost when allowed to ramble over a wall. As a climber, it requires support of that kind; and now, in mid-December, it is a beautiful object, its slender branchlets being thickly hung with shining purple fruits. Unlike many berry-bearing plants which vary their display in alternate seasons, Billardiera never fails to yield a full crop of its fruits, which in shape and colour are in such striking contrast to the slender, dingy yellow flowers which precede them.

We have never succeeded here in keeping Daphne Cneorum. which is certainly one of the choicest members of a very charming family. We have given it lime and withheld it; the result has always been the same; the plants flower well for a year or two, then begin to dwindle and ultimately disappear. I would be grateful for advice about its treatment. Would it relish moraine conditions?

If these notes should reach the eye of a generous Irish lady, who some years ago introduced me to the variety of Prunus subhirtella, named autumnalis, and gave me a plant thereof, she may care to hear that it has grown well and is now, in mid-winter, a very pretty object, its slender branches wreathed with small, white flowers. These, no doubt, will be destroyed by the frost which is pretty sure to follow the long spell of mild weather we are having; but they will be succeeded by others, for this bush possesses an inexhaustible reserve of blossom, continuing to flower on every favourable opportunity until far on in spring.

I have read and heard complaints about the unsatisfactory behaviour, in some places, of the beautiful white variety of Colchicum speciosum which was raised by Mr. Backhouse, of York, some five and twenty years ago. Mr. E. A. Bowles, in his useful handbook on the genus, describes it as requiring somewhat more attention than the ordinary form, and recommends replanting the corms every second year. That must depend upon soil and climate. Here, although the white form does not spread in grass so freely as the common and highly-coloured forms, it increases rapidly in garden soil. Each of three corms, for which I paid a lavish price when the plant was a novelty, have grown into clumps like those shown in the photograph sent herewith (Fig. 235), and have given many offsets to be planted elsewhere. *Herbert Maxwell, Monreith.*

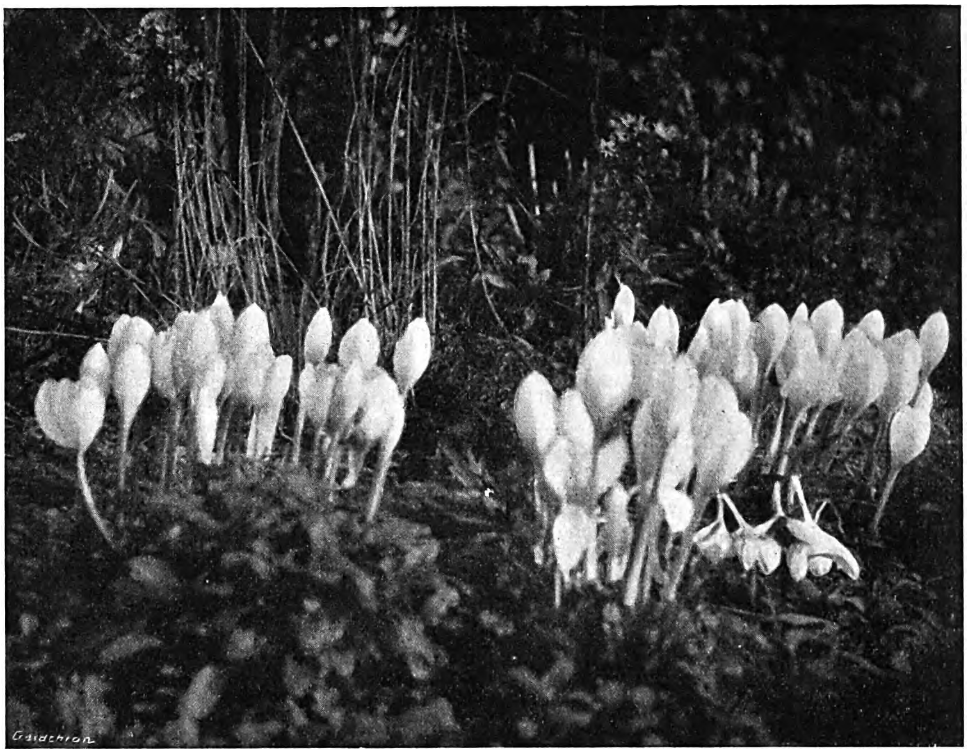

FIG. 235.—COLCHICUM SPECIOSUM VAR. ALBUM AT MONREITH.

NOTES FROM A WELSH GARDEN.

A GARDEN containing a considerable area of woodland, with running water, owes much to its Ferns, and at no season are these more delightful than in winter. One may miss many of them, but even some of these retain until spring the russet and tawny hues of their faded fronds, hues which are responsive to almost every change of light and humidity, and which ensnare the fugitive crystals of the hoar frost with an even more cunning artifice than the evergreens. Perhaps the Bracken, pest that it can be, is still without a rival as a glade Fern, whether we regard its stateliness and stature in summer, the autumn colour it wears with such peerless grace. or the rusted fronds with which it covers the woodland floor in winter.

Growing as they so often do in close company, the Male Fern (Nephrodium Filix-mas) and the Lady Fern (Athyrium Filix-foemina) are apt to lose a little of their respective distinctions in the height of summer, yet there are few hardy Ferns of similar nature which show such a marked difference as do these at this season. The reason, of course, is that while the Lady Fern is extremely susceptible to frost, the fronds becoming brown and crumpled often so early as October, those of its companion are not only evergreen, but singularly hardy. If the enormous shuttlecocks of the Male Fern, which along my little stream have exceeded four feet in height, lack the elegance of those of "the lady," one cannot be too grateful in mid-winter both for their defiant green and handsome poise and that contrast which they exert among the ruddy browns of their fallen comrades.

Another big Fern which is always a striking object in the winter garden is Aspidium (Polystichum) munitum, which will often exceed the Male Fern in stature and make a dense mass of fronds four or five feet across. It is this Fern which is often such an impressive feature in the forests of north-west America, but it is perfectly hardy here. The hard and glossy evergreen fronds remain for several years, the older ones being a deep bronzy-green, especially when much exposed. This noble species is naturalised at Ro Wen, but is not very generous with its self-sown progeny. The Scolopendriums are also at their best just now and, with the Blechnums, should continue to prove their great value in the woodland until spring green comes in again. Hart's Tongues do not make the splendid growth in this valley that they do on the limestone—in Anglesey, for example—and for the same reason, presumably, their seedlings seldom occur where there is any prospect of their "making good." One may find a hundred infant Hart's Tongues on a square yard of mortared wall where they have no possible chance of maturing, but never a single one in the rich, moist soil by the brookside in which transplanted specimens do so well.

Among the wall or rock-garden Ferns which are particularly happy at the moment is Ceterach officinarum, happy as the Ramondias with which it associates so delightfully. This unique little Fern, however, which was the original owner of the generic term, Scolopendrium (thus offering one a hint as to the application of that name), is extremely shy in naturalising here, nor is it at all common in the wild state in this locality. The creeping, mat-forming, Lomaria alpina is also a dwarf species which cannot be passed by at this time of year, for its low, dense masses of dark green, bronze-tinted, overlapping fronds are always a refreshing sight. This little Fern is indestructibly hardy in spite of its Antipodean origin, so hardy and robust indeed, that it must not be planted without due allowance being made for its spreading nature. It makes a useful and appropriate carpeting for the rather thin-habited and rambling L. procera, a hardy evergreen New Zealander, three feet tall, and a distinctly beautiful species for a wind-sheltered spot.

Gaultheria nummularioides is a first-rate plant for associating with Ferns, and it rarely looks better than it does to-day. Nor will anyone with winter foliage in view omit to plant, and plant freely, Cyclamen neapolitanum, which is well worth growing for the exquisite form and colouring of its leaves alone. Corydalis ophiocarpa and C. cheilanthifolia are not less attractive in their own way, the elegant lace-like foliage, especially of the former, developing in autumn charming and delicate shades of bronzy-yellowish-green with a sheen of lavender-blue.

In spite of an unusually mild, if wet and windy, autumn, Erica darleyensis is unusually late in flowering this season. November usually brings the first of its cheerful rose-pink blossoms, but here we are in the middle of December and not a bud is yet showing colour. That excellent foliage Heath, Calluna vulgaris var. cuprea, usually so effective at this season in its glowing masses of bright yellow and ruddy-bronze, was entirely destroyed by frost last winter. But the Heath slope never loses its interest and charm. The latest of the Cornish Heaths are still giving colour, and to the infinite diversity in the gentle tones of green which pervade the various groups may be added the charm of the dried flower heads, which range from an almost white ashen-grey to fawn and tan, cinnamon and rust-red. But this winter-colouring of the Heaths is going to meet a serious rival in the foliage tints of the dwarf Rhododendrons, once the colonies of these fill up. *A. T. Johnson, Ro Wen, Conway.*

TREES AND SHRUBS.

ZENOBIA SPECIOSA.

Although Zenobia speciosa was introduced from the eastern United States so long ago as 1801, it is only during comparatively recent years that the value and decorativeness of this lovely Ericaceous shrub have received recognition, and even now it is not so widely grown as it deserves.

It is a deciduous or semi-evergreen shrub of loose habit, the slender, smooth growths attaining a height of three feet or more. These are furnished with glossy, fresh green leaves, oblong-ovate in shape, pointed or rounded at the apex and tapering at the base, up to two-and-a-half inches long and with shallowly-toothed margins.

The large, Lily-of-the-Valley-like flowers are very attractive, for they are borne in pendent clusters of four or five on slender stalks from the axils of the leaves on the upper portions of the growths of the previous season. The flowers are pure white, bell-shaped, with five shallow, slightly recurved lobes.

To secure the full beauty of this shrub, the flowered growths should be cut back so soon as the blooms have faded, the flowering season being during the latter part of June and early July.

Beautiful as Z. speciosa is, it is even surpassed in attractiveness by its variety pulverulenta, given by some authorities as a distinct species. It agrees with Z. speciosa in all the chief characteristics, the only difference being—and herein lies its superiority, so far as decorativeness is concerned—the young shoots and foliage are furnished with a mealy, bluish-white, waxy covering which, combined with the white, waxy flowers, produced even more freely than in the type, imparts to the whole plant an air of refined charm. Cutting back the flowered growths is even more important with Z. s. var. pulverulenta than with the type, as only by such treatment is a plentiful supply of young growths assured.

There is also a variety called L. s. var. quercifolia, stated to be a curiosity, with the margins of the leaves shallowly lobed and waved.

Zenobia speciosa flourishes in peaty soil and may, together with the variety pulverulenta, be employed very effectively in light, open woodland. *M. W.*

THE GENUS PRIMULA.

(*Continued from p.* 491.)

URTICIFOLIA (Maxim.). Nettle-leaved P. (Souliei).

A delicate and beautiful species with tiny tufts of smooth, flaccid, membranous leaves with broadly oval, blunt blades, gradually tapering to very broadly winged stalks, in all about half-an-inch long; margins very deeply cut into lance-shaped-oval, pointed teeth. Flower stem somewhat flaccid, half- to three-quarters-of-an-inch tall, bearing an umbel of one to three rich pink blossoms. Corolla about five-eighths-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindrical, about twice as long as the calyx. *Gard. Chron.*, 1915, Vol. LVIII, p. 323, Fig. 114.

Grows in damp crevices in limestone rocks, frequently in cool, moist moss, in positions facing north, on the mountains of western Kansu, in north-western China, at very great elevations above sea-level.

Culture: It should be grown in peat, limestone chips and chopped Sphagnum-moss, in a cool, moist spot in the rock garden, with protection from damp in winter.

VAGINATA (Watt). Sheath P. (Cortusoides-Geranioides).

A small-flowered, dwarf, deciduous perennial species from the eastern Himalayas with a woody rootstock which produces a sparse tuft of rounded leaves about five-eighths-of-an-inch across, arch-shaped at the base, borne on slender, rounded stalks about five-eights-of-an-inch long, dilated, and sheathing at the base; margins divided into seven or more rather obscure lobes; both surfaces more or less smooth or downy. Flower stem smooth, slender, two to four inches tall, bearing an umbel of three to six lilac blossoms on stalks of varying length. Corolla about three-eighths-of-an-inch across, with very broadly heart-shaped lobes which have two to four large, sharp teeth at their tips; tube cylindrical, longer than the calyx, with a ring in the mouth.

This species grows in shady places, in clefts in rocks, and is apparently confined to the neighbourhood of Laghep, in the Sikkim Himalayas, at about 10,000 feet above sea-level.

Culture: It should succeed in friable loam and leaf-soil, in a cool, damp, shady spot, with protection from severe frost and damp in winter.

VALENTINIANA (Hand.-Mazz.). Valentine's P. (Amethystina).

A handsome, dwarf species with very deeply tinted blossoms. The short, thick rootstock is clothed with broadly oval, sharply tipped, rigid scales about half-an-inch long; the tufts of pale green, rigid leaves have egg-shaped blades tapering to obscurely winged stalks, in all three-quarters- to one-and-a-quarter inch long; margins entire or undulately toothed; upper surface pale green, pustular, underside pale, thickly dotted with pitted glands. Flower stem slender, one inch to three inches tall, bearing one or two dark or deep cherry-red, nodding blossoms, on stalks up to half-an-inch long. Corolla fleshy, broadly funnel-shaped, about half-an-inch across, with rounded, undulate, entire or cleft lobes; tube cylindrical, about as long as the calyx. Flowers in June and July. Not in cultivation.

This species is found in open alpine meadows, on the mountains of north-western Yunnan, near Buschao, also in south-eastern Tibet, on steep slopes in dwarf alpine turf at 13,000 to 15,500 feet above sea-level.

Culture: Peat, loam and limestone chips, in an open, moist, well-drained spot, with protection from damp in winter, are the conditions indicated. *A. W. Darnell.*

(*To be continued*).

NOTICE OF BOOK.

Gardening in the Southern United States.

While this book* is primarily intended to help cultivators living in the warmer parts of the south-eastern United States, it contains a good deal of information of a general and, what may be termed, theoretical nature which will make it useful to anyone seeking for the underlying principles that govern the practice of horticulture. These principles are in essence the same in whatever climate the cultivators lot may have been cast. The chapters dealing with such subjects as climate, soils, drainage, soil acidity, treatment of wounds in trees, propagation, fertilisation of soils and so on, have a general application and are very well written.

In regard to the subject of soil fertilisation, a description is given of a method of feeding trees which is very interesting and seems worthy of trial here. We all know the difficulty of feeding trees growing on lawns. The best way, of course, is to strip off the turf so far out as the roots extend, prick over the surface soil and apply a six-inch dressing of farmyard manure. But the unsightliness this method involves, even if only temporary, makes it objectionable in many places, especially where the ground so treated is visible from the living rooms of the house. This book describes a plan which, although it may not be as helpful to the tree as the one just referred to, does bring plant food directly to the roots without materially disfiguring the lawn. The author calls the process "plugging." A light steel bar sharpened at one end is thrust into the ground and twisted about so as to make a funnel-shaped hole one foot or more deep and three or four inches wide. This is then filled with fertiliser. Bone meal is recommended, which is very safe and lasting, but slow in action. Dried blood or guano would, perhaps, be better. The holes are recommended to be three to four feet apart over the root area, but for large trees it is of no use making them within several feet of the trunk.

---

* *Gardening in the Lower South*, by H. Harold Hume. New York: The Macmillan Company.

The book is well illustrated by reproductions of photographs. Especially attractive is one of the Royal Palm (Oreodoxa regia), showing an avenue in Florida of this noble tree almost rivalling in stateliness the famous one at Rio de Janeiro. It is a well-written work and should prove a popular book in the south-eastern United States, and even in parts of the British Empire with a similar climate.

WOODLAND GARDEN.

GALAX APHYLLA.

This is not a plant that will excite the senses of those who look for colour display, but a humble woodlander whose claims for attention are exceedingly modest. Yet, for associating with Shortias, Pyrolas, hardy Ferns and the like it is one that few would care to be without. Indeed, it is so much easier and more permanent than many of its companions of the above description that what it may lack in quality it more than makes good by its perennial good nature.

Galax aphylla, which came to us from northwest America in 1786, makes a slowly widening tuft of deep green, leathery leaves which are roundly heart-shaped, highly glossed and held erect on stalks some eight inches or so in length. This foliage is evergreen and not less delightful in the winter garden than it is when freshening with new leaves in spring, or when it falls into line with other autumnal subjects by assuming rich tints of crimson and bronzy-purple. About midsummer the flower spikes are thrust up to the height of a foot, erect and finely-tapered racemes crowded, with small, milk-white blossoms, and these carry-on for several weeks.

G. aphylla will grow in any cool, vegetable soil. While it is not out of place in the shadier parts of the rock garden or the mixed border it is never, I think, quite so delightful as in some woodland bottom where there is leaf-mould and stones for its underground runners to ramble through. It is perfectly hardy, does not "run" unduly, and is by no means difficult to establish, even if a little leisurely at first. There are, it is stated, two forms, one having larger leaves than the other. All I know of them is that plants received from nurseries labelled G. a. var. macrophylla have slightly smaller leaves than the one I have always regarded as the type. *J.*

BROWN ROT OF APPLES.

It appears that the dry weather during the summer of 1929 was beneficial in checking the spread of fungus diseases—and both Apple scab and Apple mildew have been kept down to a considerable extent by the dry conditions. This is to be expected, in view of the relation between the amount of moisture in the atmosphere and the development of such fungi. It is known that the Apple scab fungus requires almost continuous wetting of the foliage for some time for its successful spread, and almost all fungus spores require a degree of humidity for their germination.

Despite the dry summer, however, the fungus, Sclerotinia fructigena, where present on trees seemed to have no difficulty in spreading. This fungus causes the well-known brown rot of Apples, both on the tree and later in storage. One of its chief methods of surviving the winter months is by means of the so-called mummied fruits. These fruits are Apples which have been destroyed by the disease, and ultimately reduced to small, dry, shrivelled bodies. They will often remain on the tree through the winter, and if not removed will produce, on the approach of summer, a crop of spores capable of infecting the young fruits. In the examination of trees for disease symptoms during the past summer, the importance of removing these "mummies" was clearly manifested.

Careful examination of any spur carrying diseased fruits revealed the presence of a mummy either on the spur or on a near-by branch, often almost hidden by the foliage. The accompanying photograph (Fig. 236) shows a spur taken in August from a tree of the variety Scarlet Pearmain. The mummy (a) was the source of infection, causing the decay of the other fruits. Of these, (b) was almost completely rotten, while (c) had already become infected. In such cases the disease was spreading from these mummies as initial points of infection at a time when no rain had fallen for weeks and when most of the varieties were far from ripe.

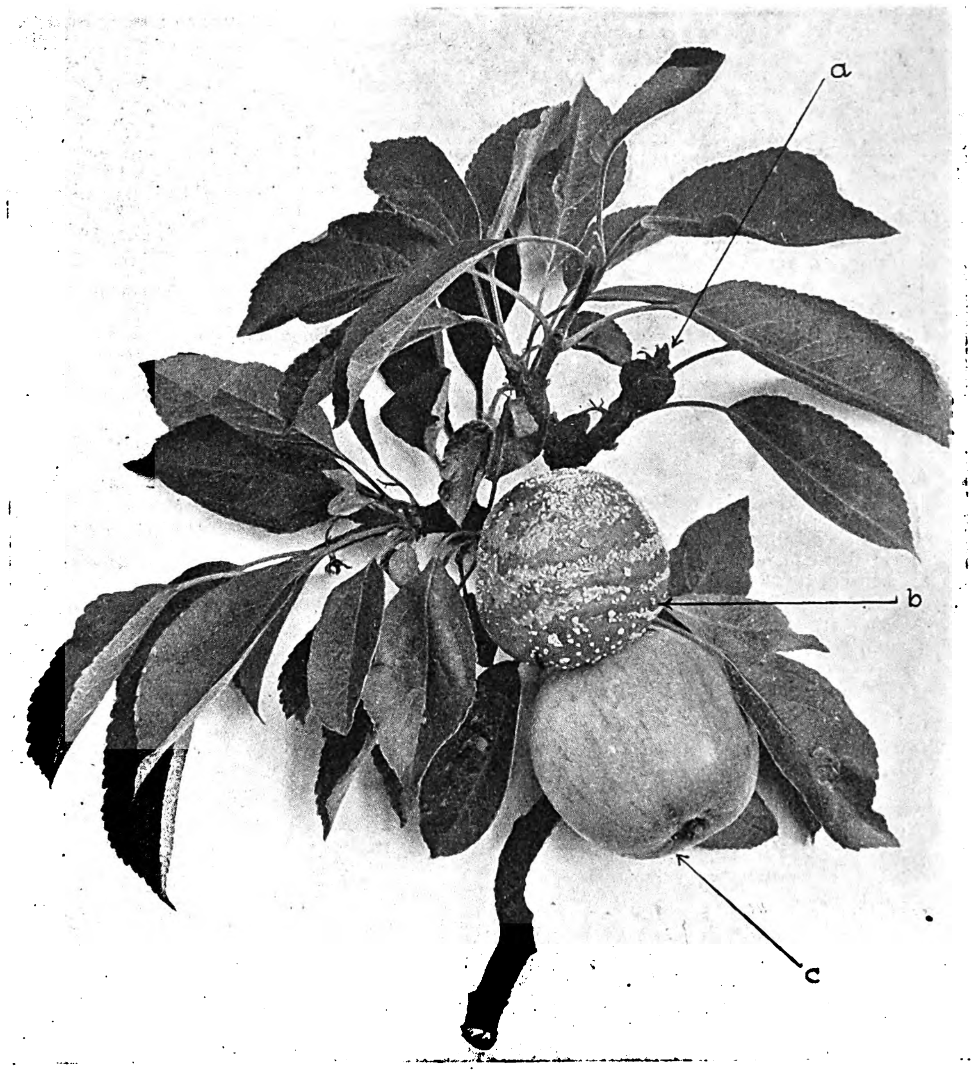

FIG. 236.—BROWN ROT OF APPLES.

It is evident that much loss can be suffered by neglect of this one point of removing and burning, if possible, every mummy from the trees. As the fungus is known to hibernate also in the spur or even the branch of some varieties, infected spurs and all dead wood should be cut out as an additional precaution at the time of pruning. *D. E. Green, M.Sc., Royal Horticultural Society's Gardens, Wisley, Surrey.*

NOTES ON INSECT PESTS.

Many of the common insect pests of fruits and vegetables were not nearly so common last summer, in many parts of the country, as they were the previous year. A number of orchards that were not sprayed last winter with a winter wash were reasonably free of insect pests the following spring and summer, and such familiar insects as the rosy Apple aphis, the Hop-Damson aphis, the green Rose aphis, the black fly of Broad Beans, and the Cherry black fly, were not noted in many plantations or gardens.

It is generally considered that very cold spells of weather during February and March destroy many of these insects in their winter stage, and thus the cold weather theory is put forward to explain the absence of pests this summer. However, the cold weather of the latter part of February and March did not appear to affect the winter stages of insect pests to any marked degree, and it was noticed in many instances that the eggs developed in a normal manner in the spring in spite of the cold spell of weather earlier in the year.

The writer is of the opinion that the eggs of many of the common pests were not present on the trees last winter, and this fact alone would account for the scarcity of these pests during spring and summer.

The eggs of Hop-Damson aphis, the winter moth and the Apple sucker were required for experimental purposes last winter, and after searching for specimens on Apple and Plum shoots in neglected plantations, for a number of days, only a very few scattered eggs were found, and the opinion was formed that the egg population of these insects was very much below the average.

Now, if there were any correlation between the weather and the absence of insect pests last summer, it would seem more reasonable to suggest that the weather had some influence upon the insects, at the period when they were depositing their eggs upon the trees, namely during September and October. Unfortunately, the position is just the reverse this winter, and many of the common insect pests are more numerous than ever, especially the insects which attack fruits.

The eggs of the Apple sucker, the green Apple aphis, the Hop-Damson aphis, the winter moth and the fruit tree red spider, can be seen without any difficulty, even by the layman, in almost every plantation. The eggs of the winter moth are exceptionally common in many plantations in Kent.

In view of the fact that the eggs of so many pests seem to be abnormally prevalent this winter, growers and gardeners are reminded that the winter spraying season has commenced, and that many of the troublesome pests of fruits may be destroyed by spraying the trees now with a good brand of tar-distillate winter wash. *A. M. Massee, Acarina, East Malling.*

HEDGES.

HEDGES serve many purposes, such as backgrounds for herbaceous borders, as shelters, or again, to divide one part of the garden from another. No matter what purpose the hedge is to serve, or the kind of plant to be used, it is wise to remember that the plants will occupy the site for a long time; therefore the ground should be thoroughly prepared and enriched, if necessary, before the hedge is planted.

There are many shrubs suitable for forming hedges, but the selection will depend a good deal upon the nature of the soil, the purpose of the hedge, and the amount which the intending planter is prepared to spend. For evergreen hedges, Yew and Holly are undoubtedly the best, for although slower in growth than many others, when fair sized plants are used they make a good hedge in a few years' time. If a Holly hedge is to be made, defer the planting of this until the late spring; Yew may be planted any time after the end of January, if weather conditions permit. Cupressus Lawsoniana and C. L. var. Triumph of Boskoop make good hedges in a comparatively short time; the latter is of a glaucous blue colour and is very attractive during winter. Thuya Lobbii is a quick-growing evergreen of a pleasing shade which withstands clipping well, and soon forms a dense screen; incidentally, this is used extensively and with great success as background hedges for herbaceous borders in the gardens at Glamis Castle. Cupressus macrocarpa, although rapid in growth, is not to be recommended as a hedge plant, as it has a habit of dying out suddenly, leaving unsightly gaps in the hedge within a few years. For low or medium-sized hedges of an evergreen nature, Lonicera nitida is in great demand at the present time. This plant does well on many soils and makes a pleasing hedge, but it certainly is not a success for this purpose on the light, hot soil of Wisley.

Nothing is more pleasing and permanently attractive than Lavender, with its grey foliage and spikes of flowers, if only a low, dividing hedge is required. Deciduous hedges may be formed by Beech, Hornbeam or Myrobella Plum, among others. Hornbeam has the advantage of retaining its brown leaves farther into the winter than the Beech. Myrobella Plum is vigorous growing and soon makes a hedge that is practically impenetrable. Delightful hedges may be formed by using various Roses, some of the Penzance Briars being especially useful for this purpose, also several varieties of the Wichuraiana type, but they call for more care than ordinary hedge plants. *R. F.*

INDOOR PLANTS.

CESTRUMS.

NOTHING is more delightful to the eye during these dull cold days of the year than a well-flowered bush of this cool greenhouse Solanaceous subject, often known as Habrothamnus elegans and a native of Mexico.

The rather small, purplish-red flowers are borne in enormous numbers in dense terminal cymes, the weight of blooms giving each spray a rather pendulous habit.

The leaves are entire, ovate-lanceolate in shape, with the under surface covered with a fine down, as also are the young stems.

This Cestrum is ideal for planting out in a border in a cool house or corridor, where a winter temperature of about 45° is maintained. It should be placed against a wall or pillar, where sufficient wires or other supports are available to allow the plant to climb, as it is of a semi-climbing nature.

Cestrums delight in a free, rich soil, both when planted out or grown in pots. When the latter method is adopted, space for the roots should never be stinted.

They are propagated by means of cuttings taken during August and potted on when sufficiently well rooted.

Cestrum aurantiacum, from Guatemala, has orange-yellow flowers rather larger than those of C. elegans, the five-pointed edge of the flower tube being turned back considerably. Both the stems and foliage of this beautiful species are glabrous, and the margins of the oval leaves are somewhat undulated. This Cestrum is very suitable for growing as a pot plant.

C. Newellii is a variety of C. elegans and is even a bigger favourite than the type. The flowers are hairy, bright scarlet in colour, with an orange reverse to the turned-back lip of the tube. The leaves are a very pleasing shade of bright green and contrast to a marked degree with the blossoms.

C. Newellii is best grown against a wall. *F. H. Wright, University Botanic Garden, Cambridge.*

NEPHTHYTIS PICTURATA.

NEPHTHYTIS picturata is the most decorative of the few species in this genus of tropical Aroids. It is an ornamental foliaged subject, introduced from the Congo about forty years ago. The specific name picturata suggests its general appearance, the raised, upper surface, between the dull green sunken veins of the large, hastate leaves being conspicuously feathered and blotched with white.

N. picturata grows about two feet high and, spreading by means of stolons, which produce growths at intervals, eventually forms a dense clump of foliage. By reason of its spreading habit, it is seen to best advantage when grown in receptacles of somewhat large dimensions, pots or half-pans from eight to ten inches in diameter being suitable. For its maximum development, it requires a considerable amount of heat and moisture during the growing season, and it should be potted in a coarse, open compost of fibrous loam, leaf-mould and sand.

HEMIGRAPHIS COLORATA.

THIS prostrate growing tropical herb, with foliage of an unusual combination of purple and silvery-grey, makes an uncommon edging to the plant stage in a warm house. Although allied to Ruellia, a genus containing several showy flowering species, Hemigraphis colorata is disappointing in that the flowers, produced in short, stiff, terminal spikes, are inconspicuous.

The best results with this subject are obtained from fresh stock raised annually from cuttings of the young shoots, inserting several around the inner edge of a small pot and placing them in a brisk, moist heat. So soon as rooted, the cuttings may be potted singly into three-inch pots, which are sufficiently large to carry them through the season. The slender, wiry main stem may grow eighteen inches in length by the end of summer if the cuttings are rooted in spring; it branches freely at the base. The opposite leaves, on long petioles, are about two-and-a-half inches long and two inches wide. *Jonathan Fiona.*

HOME CORRESPONDENCE.

Lonicera nitida.—With reference to Mr. C. Nicholson's enquiry (p. 430) as to the treatment necessary to ensure flowers and berries on Lonicera nitida, this species, as with the majority of the bush Honeysuckles, is very inconsistent in flowering. A probable explanation of its spasmodic efforts is that the flower buds are cut by the severe late spring frosts we experience every year. It has been observed, however, that when a plant makes luxuriant growth the flowers are very sparsely distributed, even in favourable seasons, but a hedge about two feet high, sandwiched between a gravel path and the top of a retaining wall, and apparently fighting for its existence, flowered more freely than any other plant of the species in the garden. Since writing of the beauty and utility of this shrub, I have had the pleasure of visiting Lord Sandwich's gardens at Hinchingbrooke, where, besides some excellent clipped hedges of L. nitida, over seven feet high and four feet through, I was very interested to see some plants trained up wire-netting, which had attained a height of twelve feet, and from their healthy appearance will grow still taller. Mr. Prowting, the head gardener, informed me that the plants were placed there about nine years ago, and by constant clipping he has made one of the most effective evergreen screens possible. *H. A. P., Brampton, Hunts.*

—— Your correspondence on Lonicera nitida seems to me very conflicting and misleading. With regard to the hardiness of it, I consider it quite as hardy as the common Laurel. I have specimens of this evergreen Honeysuckle eight feet ten inches high and quite four feet through, in various parts of my garden, fully exposed. Last winter we had frost below zero. I saw nothing to convince me Lonicera nitida was not "perfectly hardy." A few shoots made after clipping in the autumn drooped, but they soon recovered. The parent plant on the west front of my cottage is quite thirty feet high and the same in width. Other plants are doing equally well on the south and north of the house, and I should have planted it on the east side had it been possible. I clip them quite hard twice a year, and this keeps them neat and very dense, and I propagate my plants by layering, the layers soon rooting and giving good specimens to start with. I have not noticed fruits on the pyramidal plants, but those on the walls often produce them. When in flower, the bees are frequent visitors to L. nitida, *John Butler, RoseCottage, Kidlington.*

The Need of Education for Gardeners.—Your correspondence on "The need of Education for Gardeners" becomes more interesting week by week. The concluding remark by Mr. Mead (p. 450) that "No gardener, through study, and education alone, will ever fathom the practical side of horticulture," shows how far we have wandered from Mr. Kennedy Bell's original letter. Mr. Bell expressly states therein that the "actual theory and practice of gardening" is in itself "a fairly extensive subject," and that only in the winter months has the gardener time for the study of allied subjects. No one with any wits at all would expect to succeed in horticulture without a thorough grounding in practical gardening. Conversely, we must realise no one will ever fathom the practical side of horticulture without extensive study and patient enquiry. Nature does not part with her secrets so easily as that. As one who has been of late years through the mill of both the practice and theory of gardening, I should like to state that the question, in the present day, of suitable theoretical training for young gardeners, turns more or less on the question of accessibility to suitable centres for such training. In or near our large towns, and doubtless some of our smaller ones, the facilities for night classes are ample and every assistance is rendered to aspiring and promising young students. The young gardener who allows a few difficulties of a minor character to stand in the way of attending these classes is most probably of the type whose failure at any subsequent examination is already assured. The same remark applies to any who allow the need for recreation to absorb all their leisure hours. For those, however, in the remote country districts, I would commend the adoption of some such proposal as put forward by Mr. Bain (p. 430) of correspondence courses, to be run either by the Royal Horticultural Society or by the County Horticultural Instructors. It is in these districts, I feel sure that losses of promising material are annually taking place. Only by some such means will the status of our profession be raised, both in financial matters and in public esteem. *George L. Soater, N.D.H.*

—— In these days of change and decay, it would appear that, generally, what was formerly recognised as a "hall-mark" of efficiency, is no longer an asset that, by itself, is of any avail in advancing the "status" of the individual, be he gardener, or follower of any other calling. There must be education, but no one will gainsay that a good education is within the reach of all nowadays; it is obviously not the lack of education that prevails, but rather the application afterwards, or the consistent striving after improvement on the rudiments inculcated at school. It is possible that the importance of a gardener's calling is not sufficiently engraved on the mind of the majority of those who have selected the cult as a means of livelihood. Most assuredly, to my mind, the trend of the public at large is to focus the gardener as a human instrument of insignificant moment. We in the seed trade, as members of a branch of the profession, value the skilled gardener at his true worth, and covertly lament the fact that he is not more universally appreciated—but who is to blame? Servility is not desired by the broad-minded employer, albeit one is constrained to maintain that in too many cases, the gardener assumes the rôle of the brow-beaten serf, who quails at even suggesting anything that should come spontaneously from the practical man, as opposed to the unpractical suggestions of an employer. Right methods should always be insisted on, coupled with that deference due to those in authority; for by such means only will practical wisdom assert itself and hold its own. Education, then, can be applied as a means to an end, for few can withstand that bulwark of common sense, attributable to a correct early training fitly applied. One fully realises that these remarks do not apply to all gardeners, for there are left some gentlemen in charge of the few estates which are yet being kept up, whose positions are unassailable, by virtue of their innate tact and practical wisdom, two attributes that are not always the result of a superior education, but rather that rare gift of sound, stability and doggedness that befits the controller of a large establishment, in many cases, for a long sequence of years, and at the end of it a glorious heritage, which enables him to finish the course begun and continued so long, not by dint of anything but an ordinary education, but by that mastery of practical detail and consistent will-power, coupled with proper respect to those in authority. What our good friend the gardener lacks to-day is not general education, or, indeed, sufficient practical knowledge of his craft to stand him in good stead, but rather sufficient "ego," whereby a greater amount of respect and acknowledgment as assets of consequence, is engendered in the minds of an unappreciative public. With reference to remuneration, is it not conceivable that this may be automatically augmented as a corollary to the persistence of the practical gardener in maintaining his "status" as a qualified member of an ancient and honourable calling. *Albert Upstone, Rotherham.*

—— Good posts for gardeners, non-existent several decades ago, are now available from time to time for qualified men; but it is certain that many of these posts cannot be filled, and held, by the uneducated gardener. Posts in research stations, instructorships in colleges and schools, and under county councils, and such situations as park and cemetery superintendents, head gardeners, gardener-agents and gardener-bailiffs in good private places, nursery managers and foremen (many of whom ultimately become owners of small nurseries), and commercial travellers for the leading horticultural houses, in addition to the posts in the colonies and abroad, filled by Kew, Edinburgh and Wisley, cannot be satisfactorily held by men who have no knowledge of botany, mensuration, surveying, elementary or advanced chemistry, and, what is by no means the least important, a knowledge of book-keeping. I do not, of course, mean that a man should be an expert in all the above-mentioned subjects, but a really good knowledge of one or more of them is, beyond doubt, vitally necessary to the young man who wishes to obtain, and hold, to the satisfaction of himself and of his employer, one of the posts indicated above. I should also have mentioned the inspectorate (horticultural) of the Ministry of Agriculture, where posts are from time to time available for well educated men. Brains are fairly evenly distributed among the classes, whether farm labourers, office workers, or even members of Parliament! But in the majority of cases the financial position of the parents determines whether the lad must leave school at an early age, or enjoy the great advantage of going to a secondary school, and, in some cases, a college. Many of the very clever men of the older generation of gardeners are the sons of country workers, and would have made their mark in any sphere of life, but it was essential that the boy started work at a very early age, to bring a little more grist to the family mill. The chance for these men to become well educated at school did not then exist, but conditions to-day are different, as the county councils, farm institutes, etc., are always ready to hold out the helping hand to the lad who really means to become a good gardener. This helping hand is available right through to the colleges to the really bright lad. I should like to see my future gardener allowed to remain at a secondary school until he attains the age of sixteen years, paying particular attention to botany, mensuration, surveying, elementary chemistry as applied to horticulture, and book-keeping, for the last two years of his school life. He could then proceed to a really good private garden, to a first-class nursery, or to a farm institute for three or four years, not disdaining any work that comes along, and meanwhile attending evening classes or studying some of the many good text books now available at a low cost. Then could come one or two changes to really good places as a journeyman, to acquire a good knowledge of the practice of his profession. No need to worry too much, by the way, about having to do hard work, and the clock should not be watched too closely. Hard work I stress, for I am of the opinion that the lad who has learnt to work hard and conscientiously, has little to fear in the future, provided his health is good. A year or two at either Kew or Wisley would then be of value to the young gardener, both for the excellent concentrated tuition these well-known establishments afford, and for the help they will be as a first-class place to which to refer a prospective employer. By this time the young gardener should have shown the stuff of which he is made, and should have taken, or be about to take, examinations such as his advisors or instructors consider would be of help to him in the future. He should also have made up his mind for which branch of his profession he is best adapted and inclined. For the poor boy, who has to leave school at the age of fourteen years (it will now probably be fifteen years) and who has no chance of attending evening classes, please do not despair. There are many good text books available for evening study, and Kew, Wisley or the Horticultural Section of the Ministry of Agriculture would, I am sure, reply to a courteous request for advice from a young aspirant for knowledge. The Royal Horticultural Society's Examination for the National Diploma in Horticulture need hold no terrors for the skilled practical man, who has tried to study the science of his work. At the N.D.H. Examination, as a case in point, it may be found that the man who can use tools, dig, pot and prune, will pass ahead of the man who can write about it, but cannot carry out these operations to the satisfaction of the very capable practical examiners appointed by the R.H.S. This I know from personal experience. My knowledge of botany was, and I am afraid even now is, not by any means such as I would have liked. I, however, managed to wriggle through the N.D. Hort. Examination, and the sympathy and consideration of Sir Daniel Hall, the examiner in this particular subject, will be a pleasant memory to me for many years. Keen young gardeners need not fear their examiners. If rather afraid of the N.D.H. examination, the aspiring young gardener could try the R.H.S. General Examination in Horticulture, held in March of each year. This examination comes just at the right season, after a winter's evening studies, and before the busy outdoor period. It is beyond doubt a real test of ability, and there is no great harm done if a First Class Certificate does not come at the first attempt. To once more cheer up the lad who thinks he has no chance, owing to the lack of facilities for special tuition, the writer took this examination after one winter's fairly close evening study, with the assistance of no organised classes other than a correspondence course, and yet was placed at the head of the pass list for his year; too late in life, alas, to take up the scholarship, tenable at Wisley, which goes with the highest marks at this annual examination. *Henry F. Maidment, Crichel Estate Gardens, Wimborne, Dorset.*

Tomatos for Winter.—Your readers who grow Tomatos for winter fruiting may be glad to know that Cuthbert's Scarlet King is an exceptionally fine variety. We sowed seeds in July, 1929; the seedlings were pricked off singly into sixties and then transferred to forty-eights, where they remained until each plant had set one truss of fruits, then they were potted into sixteen-sized pots, and stood out in the open until the end of September, when they were placed on shelves in fruit houses. Up to the time of writing (December 16), we have picked a fine lot of fruits, and there are many more to come. Scarlet King has all the qualities a good Tomato should have; it is a free-cropper, the fruits are large and of good shape, and of excellent flavour. *G. Spence, Walhampton Gardens, Lymington.*

Surplus Potatos.—The valuable article on the surplus of Scotch Potatos, in your issue of December 7, raises a number of interesting questions. Potatos, as you state, are now down to 30s. a ton, and at my country cottage I pay in the local shop sixpence for 5 lbs., which works out at over £13 a ton. Potatos have varied between about 18s. a ton and £14 a ton since the war, and this vacillation of prices is the curse of the industry. There are four interlocking problems. The first is to secure a standard price at an economic level, a figure which is, I think, between £5 and £6 a ton; the second is to reduce the cost of distribution; the third, to prevent dumping from abroad; and the fourth (almost peculiar to Potatos and other vegetables) to secure a market for surpluses. For all these purposes we need a pool or a distributive trust, such as exists in the coal trade in Germany to-day. Such a trust could standardise prices, if it were supported by a national policy, such as has been recently established in the New Zealand Wheat trade, where the farmer gets a first look-in at the home market at a fair price, and the deficit only is acquired from Australia. Such a trust should also, by the savings in distribution, secure a fair price in the shops, say, 1s. to 1s. 2d, a stone. Then comes the question of surpluses. I found that East Poland, where I assisted to reconstruct agriculture after the war, was provided with factories where surplus Potatos were converted into alcohol. We might provide such factories or, alternatively, we might, as is done in Ireland, make flour and admirable cakes from Potatos. A somewhat similar problem arises in almost every branch of agriculture, and needs to be dealt with on similar lines. Standard prices, organised distribution, limitation of imports and means of dealing with surpluses, are the needs. Methods of dealing with all these problems are to be found working in other countries, and have been investigated by an association. The time is, perhaps, ripe for action. The Central Chamber of Agriculture is now considering the whole problem, and no organisation is better able to deal with it. *Montague Fordham, Council Secretary, Rural Reconstruction Association.*

SOCIETIES.

HORTICULTURAL CLUB.

One of the most successful meetings of the Horticultural Club was held on Tuesday, December 10 when, following the monthly dinner, Mr. F. Kingdon Ward gave an address on his recent plant-collecting expedition.

The dinner and lecture were held in the new Windsor Castle Hotel, Wilton Road, Westminster, opposite Victoria Station. Mr. Gerald Loder presided, and over sixty were present at the dinner and the company was swelled later by several who came to the lecture only.

Mr. F. Kingdon Ward's slides included maps of the districts he explored along the Assam frontier between Assam and Thibet.

The vegetation of the district has a wide range, from a tropical to an arctic flora, for the climate varies according to the altitude, and it was in the higher, open country that the most interesting plants were found. Rhododendrons were especially plentiful, many of them epiphytic on trees, and it is only on the upper branches where the Rhododendrons get plenty of light, that they appear to flower at their best.

The members were especially interested in the pictures of the natives, the hill and river scenery, and the plants growing in their natural habitats. Photographs of primitive bridges, made usually of Bamboo, were very remarkable, especially of a circular one made with rings, which Mr. Kingdon Ward said he crossed to the middle, but no further. His trouble with the native carriers and his cutting of a bridge to prevent them deserting him, showed the difficulties and dangers that are the lot of the plant hunter in such wild parts. However, he prevailed, and was able to find many new plants of interest. The whole country is very sparsely populated—one or two inhabitants to the square mile—for which famine is responsible. Famine follows the flowering of the Bamboo, the seeds being eaten by rats that multiply in swarms, and when the food from the Bamboos is exhausted the vermin turn to the crops of the natives, devouring their means of sustenance: thus whole villages may be wiped out.

In reply to a question, the lecturer stated that Meconopsis Baileyi is always a beautiful clear blue in nature, and its dingy colour in gardens he attributed to "morganatic marriage."

Lord Swathling, in proposing a vote of thanks to the lecturer, said all present had enjoyed a most delightful evening and learned much from the delightful address and pictures given by Mr. Kingdon Ward.

BUCAREST FLOWER SHOW.

The Annual Show, which was again held in Carol Park, on November 7 to 11, was very disappointing on the first three days owing to the rain, which is very unusual at that time of year in Roumania, but Her Majesty Queen Marie, who promised to open the show, arrived in good time, with the Bishop of Roumania, Mr Sarateanu, the new Regent; Mr. G. Maniu, the Prime Minister ;. Mr. Mihalacha, Minister of Agriculture; the Princess Bibesco and many others.

The President of the Society, Mr. Charles Farando, who takes a great interest in the function and works hard to make the show a success, encounters many difficulties, as very few private gardens afford assistance, therefore it is chiefly left to the nurserymen to fill the show; there is, however, much scope for the further development of gardening in Roumania. The Society deserves more help, but it was very pleasant to hear Mr. Mihalacha state that he considered the time had come when the State should help to encourage gardening in Roumania, and he would do his best in that direction, as he was pleased with what the Society was doing.

As a whole, the show was very interesting and arranged with great skill, and thanks to the weather on the fourth day, which was perfect, the show was crowded to its utmost.

Next July, members of the Society are hoping to visit Belgium and London to see various gardens and to gain knowledge of what might be done in Roumania, so it is hoped that any Society they come into contact with will show them what can be done where there is more skilled labour. The Society is also hoping to hold a spring show in 1930.

There were some excellent groups of Chrysanthemums, Carnations and Roses, chiefly from nurserymen and seed merchants, who made some very fine exhibits. The chief competitors were Messrs. Farando and Sons who, as usual, stood first for large blooms of Chrysanthemums, well arranged in green turf, in large vases and hanging baskets; the chief varieties were Pink Turner, Edith Cavell, Yellow Turner, Daily Mail, Mona Davis and Ville de Paris. Messrs. Florian Bros. were awarded a Gold Medal for a group of Chrysanthemums massed with Primulas. Mr. Constantinescu set up a fine group of Roses, all new varieties, and well arranged. H. H. Prince G. V. Bibesco (gr. Mr. J. W. Funge), Mogosoea, was again awarded the premier prize and Gold Medal for hot-house Grapes, the varieties including Muscat of Alexandria, Lady Downes, Madresfield Court, Alicante and Maréchal Gallien, arranged with Single Chrysanthemums.

Messrs. Scheidegger Bros., who filled the centre pavilion with large Chrysanthemums, showed many new varieties, and also had a large group of Roses in splendid condition for the time of year. Mr. Dumetrescu, who put up a collection of Cacti, was awarded a Bronze Medal. H. H. Prince B. Stirbey (gr. Mr. G. Schnieder), sent a collection of new Dahlias, of very fine colour. The first girls' school of horticulture in Roumania set up a very fine mixed collection of Chrysanthemums and Begonias, while the State Boys' Schools exhibited collections of fruits and vegetables with dried Prunes, Apricots and vegetables in capital condition, which are in great demand here owing to the severe winters. This institution also showed over one hundred varieties of Walnuts, and it was very interesting to notice the different shapes and colours of the Nuts.

The interest of visitors and young gardeners was sustained by a cinema display which showed how the different plants grow from the time seeds or cuttings are put in until they are in bloom; the views included those of various European gardens. *J. W. F.*

PORTSMOUTH HORTICULTURAL.

A very interesting lecture was given before a large attendance of members of the above Society by Mr. A. Cobb, of the Reading University, on December 5, the Lord Mayor, Councillor J. E. Smith, J.P., being in the chair. The subject of the lecture was "The Charm of the English Garden," and Mr. Cobb emphasised the fact that in a general way the English garden was of the landscape type, but that we had introduced many formal styles from the Continent and also, in some instances, designs of an Oriental character, and he made special reference to the Japanese form of garden. The coloured lantern slides provided very fine illustrations of many types of gardens, and there were also many good slides of Roses, Dahlias and other flowers suitable for the embellishment of all types of borders and gardens.

CARDIFF GARDENERS'.

The fortnightly meeting of the above Association was held at The Queen's Hotel, Cardiff, on December 10, Mr. W. H. Pryce presiding. The first item after the usual business had been conducted, was an intimation of the resignation of the Minute Secretary, Mr. F. Folk, who has secured a position at Kew Gardens. Mr. Folk, who is a young and most enthusiastic gardener, has spent a number of years under Mr. H. R. Farmer in the famous Cardiff Castle Gardens, and carries the best wishes of all members with him to his new sphere of activity.

The lecturer for the evening was Mr. S. Wills, the Newport representative, a large number of members attending to listen to his discourse on "Gardening: Past and Present," which proved very interesting. Mr. Wills, by no means an old man, went far back into the old days, and in comparing them with the present, he mentioned the difference in Covent Garden; the great Chelsea show in comparison to exhibitions at the Temple in the old days; the changes in the form of gardening, giving as instances, the vast glasshouses in the Lea Valley and elsewhere; the rock and paved garden; the rambler Rose arches, and herbaceous borders, which were little thought of in the past. He dealt with many kinds of flowers which had been vastly improved during recent years.

After a lengthy discussion had taken place, opened by the veteran gardener, Mr. J. Julian, a hearty vote of thanks was accorded Mr. Wills.

The prizes offered by Messrs. N. Rees for the best five Onions, were won by Mr. W. H. Pryce, first; Mr. M. Hardwick, second; and Mr. Baker, third.

Points were awarded to Mr. Baker, Mr. J. Jones and Mr. Kirby for various exhibits.

READING GARDENERS'.

There was an excellent attendance at the last meeting of the autumn session of this Society, held in the Abbey Hall on the evening of December 16, and presided over by Mr. W. Broomfield.

Instead of the usual type of lecture, Mr. A. H. Gear, Essex Street, Reading, gave a talk on "A Prisoner-of-war's Reminiscences of Gardening in Germany." He gave instances of many events that occurred from the time he entered France to when he was wounded and taken prisoner. After being in hospital for many weeks he was eventually placed as gardener in the gardens of Baumaster Dominity, at Jessinity, and later in the gardens of Baron Von Ohlenburg, Gresse, Boisenberg. He explained the methods adopted in growing Asparagus, Strawberries, salads, Tomatos and Potatos, which were entirely different to those practised in this country.

In the competition for three dishes of Potatos, three distinct varieties, there were six entries, and some excellent sets were staged. The first prize was gained by Mr. A. E. Kirby, Amity Road, Reading; second, Mr. E. Blackwell, Foxhill Gardens, Reading; and third, Mr. F. G. Rabbetts, Bulmershe Gardens, Earley.

ANSWERS TO CORRESPONDENTS.

Grapes.—*G. H.* The Grapes were in such an advanced state of fermentation on arrival that it was impossible to diagnose the trouble. Judged by your brief description, shanking seems to be the cause of failure; the small, pointed berries are seedless. Shanking causes the Grapes to dry and wither at the stalks; sometimes only an odd berry is affected, but at other times the whole bunch may fail. The causes of shanking are many—over-cropping, injury to the foliage, chills or sudden changes of temperature, excessive dryness at the roots, or the roots getting into the cold subsoil. If the roots are at fault, the only remedy is to carefully lift them, and renew the border, using a larger proportion of porous material, such as old lime-rubble, to secure good drainage, and then re-plant them.

Names of Fruits.—*H. B.* Pear Doyenné du Comice; Apples King of the Pippins and Scarlet Nonpareil.—*C. B.* 1, Cockle's Pippin; 2, Landsberger Reinette; 3, Braddick's Nonpareil; 4, Old Nonpareil; 5, Endsleigh Beauty; 6, not recognised; 7, Madame Benoist; 8, rotten; 9, Hacon's Incomparable; 10, Bellissime d'Hiver.—*Altho.* 1, Bramley's Seedling; 2, Braddick's Nonpareil.

Rhododendrons for Everyone

By F. KINGDON WARD.

Price 3s. 9d. *post free.*

There are few gardens so poor in the conditions required by Rhododendrons that it is impossible to include some of these lovely shrubs in the scheme of planting. Never before has the would-be grower of Rhododendrons had such a wealth of species and hybrids to choose from—and all the advice and assistance he requires will be found in the pages of Captain Kingdon Ward's fascinating book.

Fee for having replies addressed to this office,* **1s.** *over and above the amount payable for* **all** *words appearing in the advertisement including* **our own address.**

SUGGESTIONS FOR ADVERTISERS.

Before writing an advertisement, it is useful to look down the column and note the information contained in advertisements similar in character to your own. Important points which might otherwise escape the memory may thus be brought to mind.

Write the advertisement in the centre of a large piece of paper (for example, a whole sheet of writing paper laid out flat) leaving plenty of space at top and bottom. If the name and address are to be included in the advertisement, place them at the end; if a box number is to be used leave a generous space at the end of the advertisement, draw a line across the paper, and place the full name and address beneath the line.

No letter, or request for insertion is required, but in case of any doubt as to the proper classification the name of the section (such as "Situations Wanted, Trade") can be placed at the head of the advertisement. Such words will not be printed or charged for.

It is important to send the correct amount in payment, as any variation causes delay (see rates at the head of each section).

No acknowledgment or receipt is sent in connection with these advertisements, but if an extra 7d. is added to the correct amount, a copy of the paper containing the advertisement will be sent post free.

An advertisement received after Tuesday may not, or received after Wednesday cannot, be inserted the same week; but if fully paid, it will appear the following week, unless countermanded in the meantime.

Advertisers desiring their Advertisements repeated must give **full particulars.** *Name and address alone are not sufficient.*

PRIVATE.

SIR ALEXANDER MAGUIRE, Hoole Hall, Chester, can with the greatest confidence highly recommend his HEAD GARDENER, who has been with him five years; a first-class gardener of ability, experience and character; excellent manager and organiser; eighteen years Head last place; 36 years' practical experience in first-class establishments; highest references. — Estate sold.—Apply, F. E. HARE, as above.

HEAD GARDENER, private or otherwise; life experience all branches; used to large scale production on commercial basis. Landscape reconstruction. Recommended as good organiser and manager.—FLETCHER, Maidwell, Northampton.

HEAD GARDENER seeks re-engagement; life experience Inside and Out, excellent testimonials, recommended from past and present employer; age 46, married; disengaged.—WARREN, Godinton Park Gardens, Ashford, Kent.

MR. CHAPMAN, Crawley Court Gardens, Winchester, can confidently recommend C. EDWARDS as First JOURNEYMAN, Inside, in good establishment; age 24.

JOURNEYMAN, age 23, requires situation, Inside and Out, or Outside Lead; 7 years' experience, good references. Please state wages; bothy, etc.—Apply, J. GRANT, Westside, Greeness, Turriff, Aberdeenshire.

MR. F. CAPP, Nostell Priory Gardens, Wakefield, can highly recommend a good JOURNEYMAN for Inside in large place, south country.

TRADE.

MAN, single, disengaged, used assisting with Tomatoes, Chrysanthemums, forced bulbs, etc., seeks work.—6, Charles Street, Hillingdon Heath, Middlesex.

THE

GARDENERS' CHRONICLE
